In March the eggs were much more fertile than in April or the early part of May. According to many poultry authorities the reverse of this should happen, as warm days and short nights are considered more favourable for the production of fertile eggs than severe weather; but we are beginning to think that this is hardly true in all cases, as for several years our early eggs have been the best, and we hear from other extensive poultry rearers that they have experienced the same thing. Why this should be so there may be many opinions. The actual reason may be nearly the same throughout. Early in the season, when fanciers first commence to hatch, they are most anxious to secure fertile eggs and strong healthy chicks, and as they secure a few of these and the season advances they may get more careless in keeping up the condition of their breeding stock; the best food and other attentions being transferred from the parents to the progeny, and a sudden falling-off is the result. Again, damp weather is, according to our observation, far more favourable to the fertility of eggs and the production of chicks than drying winds, which we all know occur frequently, too frequently in April and May. A damp corner for hatching does not seem to serve the purpose so fully as a general humidity.

Further experience, then, is forcing us to think that March is the most fertile month of the year for hens' eggs. It would be of interest to know if others are inclined to think the same. Indeed this is an interesting point altogether, and if opinion generally could be ascertained as to it, much good might follow.

Some may object to March chicks owing to their being liable to suffer from the cold for a number of weeks afterwards, whereas nothing of the kind is experienced further on; but this does not by any means always hold good, and a little shelter during April winds lightens their ill effect wonderfully.

No one about here goes in for poultry-keeping wholesale, but many of the farmers and cottagers keep a good many birds. Nowhere have we heard of any great hatching taking place. Failures are spoken of enough, and altogether as to hens' eggs the season has been, as you say, a doleful one as a rule.

Geese are kept in large quantities about here, and goslings are, as some of your garden hands would say, "a grand crop." Ten, eleven, and twelve from a dozen eggs are quite the rule. Turkeys, too, are well spoken of, but Ducks are not at all satisfactory. We have not seen one good batch of them this season, although we know of plenty of eggs having been set. They, like the accompanying Green Peas, appear to have been affected by the east winds which have all along been very prevalent.

Mortality amongst our juvenile stock was never lighter than it has been this season. We have not lost a chick from disease, and

one only or two through being trodden under the feet of the mothers. Diarrhoea is one of the chief, if not the main, afflictions to be guarded against in rearing young chicks. So long as this can be warded off other ailments will do little harm, but if this once sets in nothing is more weakening, more likely to stunt their growth, or more certain to prove fatal. We are much inclined to think that most young beginners, labouring under an acute attack of chicken fever, injure their young pets by overfeeding or not studying the weather in connection with this. At one time we went to considerable expense in buying patent meals, meat to take the place of insects, and all kinds of medicines, which latter were straightway administered if an eye was seen to close at an unnatural hour, and the insect substitutes were supplied whether the chicks had natural access to these or not, but through time we have found out that much of such doctoring is not only valueless but injurious.

In changeable hot weather nothing appears to produce diarrhoea

so much as greaves or any other substance related to them. Now our chicks have never anything of the kind, and they are certainly no way inferior to what they used to be when we were supplying them with such stuff. Soft food is not given indiscriminately. In wet or cold days it is withheld altogether, and nothing but a mixture of small wheat and barley given, and this is much more effectual in regulating the system at such times than the usual quantities of sloppy food.

In warm dry weather a little of any kind of green food, such as thinnings of Onions, the outer leaves of Lettuce, or the common Wood Sorrel, may be chopped up small and mixed with their food; but this only applies to fine weather, and chiefly to chicks in confinement, as those running on grass can select green material for themselves. There is one kind of food which we generally add a dash of to the meal before mixing that we do not recollect ever seeing advised for chicks, and that is sugar. It is well

Fig. 96.—MOTTLED JAVA FOWL.

known this is a very nourishing substance, and the chicks seem to thrive on it amazingly. It is fattening if given largely, but in moderation it keeps them in very desirable condition.—J. MUIR.

#### THE JAVA FOWL.

PARADOXICAL as it may seem, the "Java Fowl" is not a Java fowl at all, but another product of American fanciers—an American breed. A few years ago Javas were comparatively unknown. To-day breeders on all sides are "going into Javas," and the boom has fairly started. Not since the advent of the Plymouth Rock has such an important addition been made to the list of standard breeds as when, this winter, Black and Mottled Javas were admitted. The standard for them has not yet been published, but a good bird is apparent to the eye of a fancier without the book that describes it. Although good work has been done in breeding Javas, much remains to be accomplished. They are the

very best of winter layers, a large fowl, with smooth shanks and yellow skin. As a rule the handsomer birds are those of medium size, and compactly built. These have a lustrous plumage in the black variety, fine full-plumed tail, and good symmetry. The large birds are more stilty, larger boned, and not so handsome. One of the first questions that Java fanciers will have to meet is that of size. It will be found that the small birds will breed a prettier specimen, but the points to gain are fine shape, clear lustrous black plumage, and good size for market. There is no sort of doubt that this can be done, and so many fanciers are now becoming interested in the breed that it is sure to improve at a rapid pace. The material is there for a popular fowl for all classes, fanciers and farmers alike, and it bids fair in a few years to contest the prize for a practical beautiful fowl with the Plymouth Rock. As to their real origin little is known. All we positively know is that they are here, and that will answer; excellence before pedigree always. This is, however, of the Black

variety only. We know who originated the Mottled Java, and how he did it. Mr. Lattin had added to his fame as a fancier of Black Javas the honour of originating the Mottled birds. He writes us as follows concerning their origin:—

"About nine years ago I had some white hens, known here at that time as White Brahmas, but without any feathers on their legs, which were smooth, and a bright orange colour; beaks yellow, combs single, size about the same as the Javas. To commence with, a pair of Mottled Black and White chicks were hatched from these hens' eggs. As I had no other cocks on the premises but Black Javas, these Mottled chicks must have been the result of a cross between a Black Java cock and the White hens. I kept the two Mottled chicks, and next year raised five more nicely Mottled ones; the rest were White, about the same number in each brood. The next year I bred the cock from the first pair to the last year's pullets, and succeeded in getting a fine lot of Mottled chicks, a few White ones, and fewer Black. From that time I worked faithfully to improve them in breeding true to colour; till I got them so a very small per cent. of White chicks appeared. It will, of course, take some time yet to breed them all uniformly alike, as no breed will do this, but they run very true and even, all things considered. The Mottles are not always evenly distributed, and for some time the legs would be black or willow, though some prefer them mottled yellow and black, but I now have no trouble in breeding legs yellow."

[We take the above account of the Java fowl, with the accompanying illustration, from our New York contemporary, the *Poultry Bulletin*. In thus acknowledging the source from which our information is derived we do not follow the course adopted by our contemporary, in whose pages we were somewhat surprised to find a reproduction under a slightly altered title, and without the least hint as to their origin, of several of our articles upon "Practical Scientific Breeding." The taking of extracts or even single articles by some of our American friends we are accustomed to, but we think this wholesale appropriation is not the common practice of journals of repute on either side of the Atlantic.—Ed.]

#### DOVERIDGE POULTRY SHOW.

*President*—Lord Waterpark; *Treasurer*—Rev. C. J. Hamilton; *Secretary*—Mr. S. J. Adams, Doveridge, Derby.

Uttoxeter, 28th April, 1881.

Sir,—At a meeting of the Committee for promoting the above named Poultry Show (to be held at Doveridge, near Uttoxeter, on Thursday, the 3rd November next), I was requested to send out circulars giving notice of this Exhibition, with the object of securing entries.

There will be forty-one classes, of which twenty-two will be for single birds hatched in 1881. There will be a class for birds (cock and hen, or cockerel and pullet) not exceeding two years of age, first cross between any two distinct varieties of pure-bred exhibition fowls, to be judged for quality for table purposes. Entrance fee, 2s. 6d. First prize, £2; second, £1; third, 10s.

Also a Selling Class for pens of one or more specimens, not exceeding three, of any variety of recognised exhibition poultry, pure bred, not exceeding two years old; no limit as to prices. Entrance fee, 2s. No prize will be given for this class, as it is impossible to judge birds of different breeds against each other; but cards, V.H.C., H.C., and C., will be given for those pens which are of extra merit.

The entrance fee on all classes except as above stated, and Classes 40 and 41, will be 3s. 6d.; and for these classes exhibitors will be at liberty to affix a price on the birds, or enter them "Not for Sale," at their option.

Only 5 per cent. commission will be charged on sales of birds effected at this Show.

Two prizes of £1 and 10s. will be given for the general classes, and more if the number of entries warrant an addition.

The Show will be held under the usual rules, supplemented by the Poultry Club rules. Schedules of prizes and copies of the rules may be had, post free, on application, by card or otherwise. The entries will positively close on the 19th October.

It will be observed that several of the arrangements are novel; these are believed to be improvements, and it is hoped that you will testify your approbation of them by a reply to this circular, promising entries.

E. J. BLAIR, *Honorary Superintendent*.

The above circular has been forwarded to many fanciers, and seems to us worthy of comment in more than one particular. To begin with, the plan of sending round a preliminary circular with the object of obtaining, if possible, some idea of the amount of support likely to be accorded to a poultry show, strikes us as being one worthy of imitation. Of course the eventual success of the scheme and its continuation in future years must entirely depend upon the way in which the show is managed, and we may in a friendly way hint to its promoters, that as a rule somewhat

more of a guarantee for the good management of a prospective show is required than the names of distinguished patrons and honourable treasurers—viz., that it should be regulated by practical fanciers, but possibly in this case a list of the committee of management may follow with the schedule.

The chief innovation on established custom in the Doveridge prize list will be the rule that in the selling class the prizes shall be merely honorary. Of this we unhesitatingly approve for two reasons: 1, Because according to the circular "it is impossible to judge birds of different breeds against each other." There may be some slight exaggeration in this statement, but in the main it is true. We well know how perplexed conscientious judges often are at the end of their long day's work to place the prize birds properly in these classes, and how those troubled with fewer scruples award the honours in a somewhat happy-go-lucky fashion. The most careful judges usually pick out the best pen of each of three or four varieties for the three or four prizes, while perhaps the second or third best of one kind are really of that kind better than the best pen of one of the other breeds. 2, Because the custom of entering valuable birds just to win a money prize, the owner all the while intending to buy them back again, will be materially checked. The said practice has led to manifold controversies and dishonesty, and in spite of more than one legal decision to the effect that in a selling class an owner contracts to sell his birds, and therefore cannot bid for them or buy them back, is constantly resorted to either openly or through the quibbling medium of a purchase in another name or through an accomplice. Those who really wish to sell their birds will be equally able to do so from their intrinsic merit, and a doubtful purchaser will receive some aid from the commendations of the judge, bestowed in all probability more judiciously because it will not be necessary to place any pens in order of merit; those, on the other hand, who do not wish to sell will have no inducement to show in the class, and as at present defeat its very object.

Another commendable point in this schedule will be that only 5 per cent. commission will be charged on sale. It has often struck us that the customary 10 per cent. is in many cases very high and practically prevents sales by keeping up catalogue prices. Of course at such shows as the Crystal Palace and Birmingham the advantage of exhibiting birds is so great, the number of possible purchasers who must see them so enormous, that the commission is by no means excessive; but at many a smaller or local show it is simply absurd to make so large a deduction from purchase money. The Poultry Club rules are, we observe, to be incorporated in those of the show. This is a wise move on the part of its promoters. These rules were drawn up with great care by those well experienced in the difficulties which committees who wish to insist on fair and honourable competition frequently have to contend with, and will enable those less versed in such matters to steer clear of pitfalls into which they might otherwise fall.

There is a somewhat monotonous uniformity in the regulations of most poultry shows, we are therefore specially glad to hail the originality of these, combined as it is with sound sense.—C.

#### REMARKS.

15th.—Overcast; high gusty wind and much dust.

16th.—Cool and showery.

17th.—Bright and fine early, afterwards high squally wind and showers.

18th.—Wet morning; fine with bright sunshine between noon and 3 P.M., then overcast and rain; fine after 8 P.M.

19th.—Slight showers before noon, fine and bright afternoon and evening.

20th.—Cool, but fine and bright generally, shower only at 1 P.M.

21st.—Generally fine, bright and warm; slightly overcast at intervals.

Temperature almost exactly the average, the mean daily range less than last week, the maxima being lower and the minima higher. The air has also been less dry, and showers fell on five days.—G. J. SYMONS.

## ARE WE PROGRESSING?

THE thought has often crossed my mind within the last few years as to what would be the effect upon horticulture of the transitional times through which we are passing. Gardening is generally considered to be a luxury, and we know that the first effect of a diminished income is a curtailment of luxuries. How, then, can it be possible for our craft to keep its head up when the incomes of our wealthier patrons are daily growing less? Well, I have come to the conclusion that a great deal has passed for gardening of late years which deserves to be called by another name, and that real gardening has been proportionally neglected. We know that if Mary Jane when she leaves the village school, where her happy face and clean pinafore made one of its brightest pictures, suddenly rolls in the luxury of some £5 a year, she very soon becomes transformed into a different if not a prettier being. So, I believe, our wealthy classes, the patrons of horticulture, have been luxuriating, and for a time at least have, in studying how to be grand, thrown away their own inborn taste and blindly followed fashions set by persons who in many cases have no taste or refinement whatever.

But, "Hurrah!" said I the other day on opening a circular headed "School of Gardening," "we shall have it all right now. The sons of our employers will have nothing to do but pay a couple of hundred pounds, take a few practical lessons, then come back and teach us how things really should be done." Being in the neighbourhood of this said school the other day, as I do not like to be behind everybody else, I thought I would call and steal a few lessons in advance, but I was sadly disappointed. The Crystal Palace is certainly an elegant structure and worth a long journey to see; but I hope the next time I go, if such a punishment is to come upon me, that the terraces may be covered with 83,000 Foresters, as they were during my only other visit. School of Gardening indeed! Well, go if you wish to learn how not to do it. The teachers are there no doubt; one, indeed, is an old personal friend, who certainly ought to be efficient. But what should we think of the London School Board if it gave all its attention to supplying teachers and did not provide books and other appliances for instruction? Seriously, as a piece of ornamental gardening I pronounce the Crystal Palace grounds, as viewed from the terrace, to be an utter failure. The terraces are not in proportion to the building; the beds are, many of them, in the wrong places and the ugliest possible shapes; and the whole thing has a harshness which makes one feel indescribably uncomfortable, only relieved in my case by going downstairs

and looking at the fishes. Judged, then, by my experience at the Crystal Palace, my answer to the question at the head of these notes would be a decided negative. But happily I had some of another kind.

One of the things most noticeable to a countryman is the manner in which London itself is becoming ruralised. Trees are growing up everywhere as if by magic, bringing health and beauty where both are likely to be appreciated. A walk through Battersea Park, too, is a thorough enjoyment even for one who lives in one of the noblest parks in England; and even the Royal Horticultural Society's Garden at South Kensington, once a model of all that was ugly, though it would not be difficult to find some faults in it, is now becoming a very fair example of what a London garden should be.

The best example of ornamental grounds which it was my privilege to see near London, if not the best I ever saw, is that in which Wimbledon House stands, the residence of Sir Henry W. Peek, Bart. I will not attempt to describe it, but I advise all who like English gardening, as distinguished from Cockney and formal gardening, to obtain Sir Henry's permission and take a quiet stroll in these beautiful grounds without delay, for I am sorry to hear they are soon likely to be invaded by bricks and mortar. Practical gardening, too, is exceedingly well carried out at Wimbledon House, Mr. Ollerhead having many original ideas quite refreshing to one who does not like to always keep in the same track our grandfathers did without inquiring the reason why. The Orchids and Peach trees are marvels of cultivation; and the Vines, although not up to Mr. Ollerhead's standard of excellence, are such as most people would call good, and are still improving.

Another establishment where I saw plenty to admire was that which was brought into prominence at Anerly by Mr. Wills, and is so ably presided over by Mr. Bause, the raiser of those grand *Dracenas* which created such a sensation all over Europe a few years ago. I went fully prepared to see something good there, but I must confess that what I did see surprised me—house after house filled with one class of plants, and thousands of one variety in a batch so exactly similar in size and colour that they looked as if they had all been turned out of a mould; and that Mr. Bause and his assistants had nothing to do but stand them level and straight. The trade done in these plants is very great, and a house is cleared in a very short time; so that with the exception of a few specimens to show their character there was nothing but young plants to be seen, and these had evidently been grown very quickly. Mr. Bause has recently turned his attention to Ferns, which he grows marvellously well, and he has some very promising hybrid forms of this class of plants.

And now, what shall we say about Chiswick, dear old Chiswick? Well, here a few years ago we had a very striking instance that wealth and the smiles of the great may lead to positive evil. Chiswick as a centre of practical experimental horticulture is something approaching perfection; but Chiswick depriving herself of her own life blood to clothe in gaudy and unbecoming colours her profligate foster-child at South Kensington was a pitiable object. Now, happily, misfortune has taught the foster-child to be less vain, though far lovelier, and Chiswick is once more a credit to the Royal Horticultural Society. Gardeners, pay a visit, learn a lesson; and if, like myself, you cannot afford to become a Fellow, then pay a guinea annually and become a member, feeling assured that the money

will be well spent. Five thousand guineas from five thousand gardeners added to its present income and expended at Chiswick under its present able management would make it (if, indeed, it is not that already), the most interesting spot in the horticultural world, and give the subscribers a pleasure such as they can scarcely obtain elsewhere so cheaply.—WM. TAYLOR.

#### FILLING FLOWER BEDS.

THOSE who are in the habit of doing certain work at a certain and early date are liable at times to be forcibly reminded that ours is a very variable climate, and to find when early planting has been done that it would have been wise to have been less hasty in their operations. Many have already planted the greater part of their tender bedding plants with the result really of loss of time, as the cold frosty nights succeeding clear hot days most injuriously affects the previously sheltered plants. Those probably who commence bedding-out the first week in June, completing the work during the next week, will at the end of the month be the most forward.

The stock of plants with many appears to be limited in extent; in this case mixed planting will have to be resorted to, and probably will be found, if judiciously carried out, to give more pleasure than the blaze of colour obtained by massing one variety. The mixed plan is best suited to large beds, the smaller beds being most effective when planted with one or two kinds of compact habit.

In many instances much judgment is required in the selection of suitable kinds of plants for certain positions. For instance, Verbenas during an average season would inevitably fail if planted in any other but a somewhat rich retentive soil, and the Violas are equally moisture-loving. Petunias, the single varieties especially, thrive admirably in a somewhat poor and dry position. The stronger-growing Pelargoniums, both single and double, should have a dry position, or they will grow vigorously at the expense of the bloom. Calceolarias will fail in a poor soil and hot position, but good substitutes—namely, *Tagetes signata* pumila and the miniature French Marigolds, are not so particular in this respect. The soil should not be heavy and close for Iresines, Coleuses, Alternantheras, and similar exotics. Lobelias will not long continue to flower in a poor dry position, but the Golden Pyrethrum will thrive almost anywhere. Plants of a succulent nature succeed best in a light open soil. Such annuals as Asters, Stocks, Zinnias, Phloxes, and Dianthus should have a tolerably rich soil. The three first named are very effective when dotted among beds of Verbenas, Phloxes, and Petunias, which latter will have completely filled the beds by the time the Asters and Stocks have ceased flowering. The bronze, silver, and golden variegated Pelargoniums are very effective when interspersed with Violas and purple Verbenas—notably *V. venosa*; and so also in similar positions are the white and yellow Paris Daisies, *Abutilon Thompsoni*, and *Veronica Andersonii* variegata.

In the mixed borders it is very important that the different varieties are planted according to their respective heights, and if the other line consists of one variety such as Pyrethrum, Lobelia, and Cerastium, the effect will be improved. No plant should be put out with its ball of earth in a dry state, and as a rule after firmly fixing the plants the soil should not be levelled about them till a good watering has been given. By thus enclosing moisture further cold, and oftentimes useless, waterings are un-called for.

Carpet beds to be a success must be well done, and as they require a great number of neat-growing plants few amateurs aspire to them. Much, however, may be done with a quantity of small Pyrethrum for the fine lines, *Sedum glaucum* and *Mentha* for the groundwork, and Alternanthera of sorts, *Oxalis rubra*, Iresine Lindeni (pegged down), and *Coleus Verschaffeltii* for filling in the principal figures of the design. A complicated design should not be attempted by beginners; and in this case, by using hardy plants for marking out the design and for the groundwork, the beds may easily be refilled with other hardy plants for the winter.—A FLOWER GARDENER.

#### APPLE AND PEAR BLOSSOM IN WILTS—FRUIT TREE CULTURE.

I HAVE seldom seen so splendid a floral display on Apple and Pear trees as has been on the latter, and is on the former as I write this eighteenth day of May. How well we can understand the motive of our ancestors in mingling the flower garden and the general fruit garden. As an old writer remarks in some such words as these, "Verily the Apple tree is beauteous at two seasons—

when covered with blossom, and when laden with fruit." This is one reason why I have always advocated the partial admission of Apple trees, Pear trees, and Cherry trees into thinly planted shrubberies near a house. This year the blossoms have no pinched or withery look, but each petal is at its best. Last summer the trees had a rest and the sun was powerful, so the wood was well ripened, hence the result in abundant blossom, and I trust a further and fuller and more satisfactory result in fruit.

To speak of Pears first. All save Josephine de Malines have bloomed abundantly, and these trees I must attack at the roots. I would premise that I grow all my pyramids naturally, never cutting a branch unless it crosses another. I have nothing whatever to do with summer-pruning or winter-pruning; as the tree comes from the nursery so it grows, forming in some cases elegant pyramids, in others diffuse and spreading trees: of course I prefer the former. The result as to growth is that all my trees are thin, none are close bushes, but so thin that the sun warms all the wood and the air reaches every part. That this is the best and most profitable mode of growing pyramids every year makes me more certain. Old, possibly prejudiced, gardeners have seen them, and confess that I am right and the old mode is wrong. In regard to one method of checking undue growth I am a Spartan—viz., root-pruning. Thus in a strong-growing tree, whether Apple or Pear, I am unsparing; to such an extent sometimes that I have to stake the trees to keep them from being blown down. But the result is always satisfactory. Thus I have a Beurré Hardy, a Beurré Diel, and a Beurré d'Amanlis which have been fruitless, and the first-named without even a blossom until this year, and it is covered, as also the others. What I do when a tree refuses to bear, even when very severely root-pruned, I will detail when I come to speak of Apples. One fine Pear I find much liable to injury by frost—that is Napoleon; while the blossom of others near appears uninjured by an April frost, its blooms are turned into the colour of tea leaves.

I have every Apple tree covered with blossom except Peasgood's Nonsuch, which as yet has declined to show more than here and there a bloom, and has not fruited. All the others except a few of those planted last year are in full floral beauty. As to the newly planted, I am always glad when they simply grow at first, but bloom in after years.

I have spoken of root-pruning to so great a degree as to necessitate the staking of the trees for at least the year after. But occasionally I resort to stronger measures. Thus I have a Dumelow's Seedling Apple which reached me five years ago last autumn, as most of that kind do, a picture as to symmetrical form. It instantly commenced growing, but was fruitless. By a mistake it was heavily manured—it grew, of course, still stronger; I root-pruned it, but still it grew. In November, 1879, I removed it ten or a dozen yards, cutting the roots severely and supporting it by three stakes. Last year it was in feeble health, the desired check had been given; this year it is a mass of bloom. I measured the tree and found it 12 feet in height, and the lowest tier of branches right across being about 11 feet. Its proportions and pyramidal form are very pleasing. I was urged to prune it but declined, being quite sure that if I keep a tree thin, in time fruit spurs will form on every branch. This year I have my reward, for there is blossom at regular intervals on its leader and on every branch. From such a tree so managed I expect to have a heavy crop, not merely a few as in small and close-pruned trees. As to this variety, Dumelow's Seedling or Wellington, I do not find any other its equal in health and value of fruit. I often wish that its opposite as to season, Lord Suffield, was equally strong in wood and growth. Ecklinville Seedling is my next favourite, then Stirling Castle, while among eating Apples Irish Peach and Cox's Orange Pippin reign supreme. I find hardy fruit culture so interesting that I long to have more room for experiments than can be allowed in a parson's garden.

I find that excellent Apple, Summer Golden Pippin, a shy bearer. Is that the experience of other growers?—WILTSHIRE RECTOR.

P.S.—I noticed with much interest in the Journal of May 19th the account of the unpruned Pear trees at Wimbledon House. In our competition with America it strikes me as a great point to grow all our fruit trees as large as possible, particularly our pyramids, inasmuch as on size of tree depends largeness of crop. A small pruned pyramid may produce a dozen or more Apples or Pears, while an unpruned one produces many dozens; hence size is so valuable. Give with that beauty, utility, and largeness of fruit, and you have a chance of doing something; also the tree must be healthy.

PYRUS MAULEI.—I can fully corroborate Mr. Charley's remarks with reference to this handsome Japanese shrub both as to

its free-flowering qualities, and as a useful fruit-bearing shrub. At Messrs. Maule's nurseries I saw some thousands of plants ranging from a few inches to several feet in height, were all covered with their beautiful golden fruit, the weight of which, unless supported, bore the branches to the ground. I was informed the fruit was all utilised in the making of jam, and some which I tasted was very agreeable to the palate.—G. S., *Sandbeck Park*.

### DOUBLE FLOWERS.

DOUBTLESS not a few of your readers were amused and interested by "SINGLE-HANDED'S" onslaught on double flowers (page 391). I apprehend, however, that if he had been a little less sweeping in his anathemas he would certainly not be single-handed here. But he must allow that even as a variety of form a double flower has its charms; and as he is very strong on the score of variety perhaps he will kindly allow us a few in which it is admissible—nay, desirable. May I, as a worshipper of the Rose, crave for her at least that she reigns more as the "Queen of Flowers" since she has become double? Indeed, lovely as she is in her native simplicity, I apprehend no one would bestow the title of "Queen" on the Rosa canina, for the Orchids which "SINGLE-HANDED" well claims as wild would certainly disprove her. Again, could we have had all the different varieties of the Rose or Dahlia, for instance, had we been restricted to single flowers? I should say, Most certainly not; it is the doubling of these flowers that has given us these varieties; and in regard to these two flowers, the Rose and Dahlia, I cannot but think very few will be found to agree with "SINGLE-HANDED."

"Double flowers in general possess neither simplicity nor elegance, they are mostly ungainly monstrosities." Thus writes "SINGLE-HANDED," and with the words "in general" very distinctly marked. I confess I am almost disposed to agree with the sentence. Some flowers it is absolute cruelty to double, and I wonder rather that your correspondent had not specially mentioned them, I mean all the tubular flowers. Take a Petunia, a Convolvulus, or any of that kind of flower, and the person who has achieved the triumph of doubling it has, in my humble opinion, always succeeded in another thing—that is, destroying the character, and with it all the loveliness of the original. If we lose the vista down the throat of the flower and all the delicate shading by which the colour is lost as we get to this portion, and with this loss of the shading all the exquisite colour of the throat itself (for though nominally white, it has a pearliness of appearance which is indescribable), then I agree most decidedly with your correspondent—we have lost one of the greatest charms of the flower. Some flowers will not bear doubling, and it is to be regretted that the early attempts were not at once "put down." Tubes and bells certainly are spoiled by it; all flowers, like Pelargoniums, when once doubled will no longer "bear inspection;" they may do at a distance for effect, just as a character of a servant may on paper appear all we could desire, but the close inspection, like the personal interview, dispels all the enchanting vision.

I recollect a friend of mine, when the triumph (?) of doubling the Fuchsia had been discovered, saying, "Indeed he had never seen a double Fuchsia." "Have you not?" said another friend; "well, I will tell you that when you do you will wish to throw it away." Here again I agree. I always want to throw them away; they, like the Petunias, are "monstrosities." What more lovely than the Lily of the Valley? and yet a Goth has doubled it. Well, what shall I say of the successful grower? The least that he should be—well, not hung, but at least suspended from ever having a similar chance!

Poor Dandelion! a wild flower, too; "a wisp of petals!" Well, I own to having often thought, and sometimes remarked, if it had never been seen what a furore its introduction would have caused! Surely it does not deserve quite all that "SINGLE-HANDED" says of it. It is beautifully regular, and thus possesses a great charm, and I have noticed that little children are attracted to it; indeed, for some years it was the favourite flower of one of my children. I cannot help thinking that one of the reasons why it is disliked by older children is the bitterness of the milky juice, which also stains the hands and gets the small people into trouble, and hence it becomes a "hissing and a byeword." Perhaps, too, yellow is not the most favourite colour; certainly when, as in Chicory, you get a somewhat similar flower, not yellow, it is welcomed by most lovers of flowers as very pretty.

Whilst, then, agreeing very nearly with "SINGLE-HANDED," and almost joining in his protest against doubling flowers, I must confess I cannot go with him in his remarks on form. To most of us I apprehend a round outline is the most beautiful in flowers,

and—I confess it—I think with every reason. Setting aside the colour, surely the roundness of outline in the Pansy, Pelargonium, and Cineraria for instance is a great improvement on the stars and irregularities of outline, amounting to raggedness, of the flowers from which our present varieties were originally produced. I prefer the more perfect form to the greater diversity of form, and should be content with the diversities of colour to make my variety. We should still have other flowers to show us the diversities of form, as the Lilies, Cyclamen, Fuchsia, Snapdragon, and Salvias, whilst it must not be forgotten that in the foliage we have every possible variety of outline, and therefore may allow the flower to be mainly formed on the best model.—Y. B. A. Z.

### LEDUM PALUSTRE.

WILD ROSEMARY is one of the popular names by which this pretty little North American shrub is known, a title which has probably been conferred upon it because the foliage possesses a powerful aromatic odour that is particularly notable when the leaves are crushed in the hand, or immediately after a shower on

Fig. 97.—*Ledum palustre*.

a warm day. In other respects it is widely separated from the true Rosemary, and is a close ally of the Kalmias and Rhododendrons, which are so well known and appreciated in gardens. It is a compact shrub, rarely exceeding the height of 3 or 4 feet, and bears small, narrow, elliptical, dark green leaves, and close corymbose racemes of white flowers, which are very freely produced and render the shrubs very attractive at this time of year. They are especially suited for planting in the front of shrubbery borders, and being evergreen their neat habit renders them attractive at all seasons. Moderately light soil is requisite to obtain them in their best condition; but they are not very particular, and if the border is well drained little difficulty will be experienced with them.

Both *L. palustre* and *L. latifolium*, also known as Labrador Tea, possess some medicinal and economic properties. The former is said to contain qualities which render a decoction of the leaves beneficial as an external application in cutaneous diseases, and in some parts of Germany a peculiar kind of beer is also prepared from the leaves. *L. latifolium* is considered to possess tonic qualities, the leaves having been employed to furnish a substitute for tea, and they are also infused in beer, which they "render heady, and cause headache, nausea, and even delirium."

The woodcut (fig 97.) represents a spray from Messrs. Osborn and Son's Nursery, Fulham, where these plants are well grown.

NEW AND OLD PEACH TREE TRAINING.—Permit me to say that I regard Mr. Pettigrew's Peaches that produced 112 dozen fruits in three years as a remarkably good example of extension training, seeing he does not lay in laterals; but he does not give

the size of the trees when planted, nor state how much fruit he gathered the first and second years. Would he kindly do this, as he has the quantity booked? The testimony to the present condition of his trees is, to me, a particularly satisfactory point. Mr. Pettigrew's own knowledge of the system "before I was born" puzzles me, however, because he and I were both whiskerless lads at Drumlanrig Castle together, and there were then only a few years between our ages. The examples he speaks of before I was born must be only traditionary, I am afraid.—J. SIMPSON, *Wortley*.

#### AURICULAS AT SHIBDEN HEAD.

SHIBDEN HEAD, the residence of Mr. Woodhead, is situate about three miles from Halifax and five from Bradford; the nearest railway station to which is Holmfild, on the Great Northern Company's line from Bradford to Halifax, the distance from which station is about a mile and a quarter up a steep hill known as Windy Bank, and windy it is when the wind is in the west. When the top of Windy Bank is reached a short descent brings the visitor to Shibden Head, which is upwards of 1000 feet above the sea level. Here, although so high and cold, not only does the Auricula thrive but it grows finer than I have seen it elsewhere, as, in addition to the plants being robust, the yield of offsets is great. Mr. Woodhead grows his Auriculas in three houses on the eastern slope of the hill, which forms a portion of the dividing range or backbone of England, running betwixt Lancashire and Yorkshire.

No. 1 house contains the stock plants of named varieties, comprising nearly a thousand plants. Here are the large collections of named sorts, consisting of upwards of forty Col. Taylors, thirty-five George Lightbodys, the same number of Lancashire Hero, Smiling Beauty, &c. The bloom in this house was superb, the plants being well grown and the trusses large. Amongst the best were Col. Taylor, green; Prince of Greens, very large, only weak in its tube, which is nearly green. In greys as usual many were good; whilst in whites Acme, that free-growing sort raised by the late Mr. Read, was beautiful. Amongst fancies Gorton's Stadtholder was fine with twelve pips. All these plants were in glazed pots, which are evidently suitable for the purpose. Two points are particularly noticeable as regards the plants being grown in glazed pots. One is that only  $2\frac{1}{2}$  inches depth of compost is required, the lowest part of the pots being filled with crocks; and another is, that the plants do not require a third of the water which they need in porous pots. To this Mr. Woodhead ascribes the robustness of his plants, as he says that where so much water has to pass through the pots the strength of the compost is washed away without benefiting the plants.

In the next house were the seedlings, which I was most anxious to see. These were planted in shallow boxes, originally twenty-two plants in a box; of these some had bloomed in the autumn and had been removed. To see the seedlings I had to pay a few visits in intervals of a few days each, and by that means I was enabled to note a few of the best flowers; but the stock of really good flowers consists of hundreds, many of them better than any in cultivation. This can only be ascribed to the great care taken in hybridising, no flower being used for that purpose in which there was a chance of either being self-crossed or by bees. Another thing Mr. Woodhead kept in view was always to have a rich tube in one or both of the parents when hybridising, and to this fact I attribute the beautiful golden tubes his flowers possess. Another thing very noticeable was how the properties of the parents were to be seen in the offspring—a sure proof that the work had been properly done. It was particularly noteworthy the very small percentage of pin-eyed flowers there was amongst them, whilst in only three instances were good flowers spoiled by having a pin eye.

House No. 3 contained seedlings which had bloomed in autumn and had been potted at that time. These plants were very robust, and amongst them were some very fine flowers. There was also a number of seedlings in boxes from seed sown about Christmas, 1879. Many of these were blooming on small plants, a few of which were very promising, but the major part of these will not bloom until next autumn or spring.

Of fancy flowers there were some with immense trusses nearly like Hyacinth stems owing to their erect growth; whilst some flowers were nearly white, drab, buff, puce, &c. In no case was there an absence of paste, nearly all the flowers except Alpines having an abundance of it. This is rather strange, as I recollect when I first commenced growing Auriculas thirty years ago I was told by old growers that some varieties would yield only Alpine flowers. This must have been caused by Alpines being grown amongst edged flowers, and most probably crossed by bees, which is nearly an impossibility in hybridised flowers. Such flowers the bees will not visit, having no doubt an aversion to a mutilated

flower. I may say that fully one-half of the seedlings will be grown till they are fairly proved, all possessing more or less good properties. Mr. Woodhead's garden must have been visited by hundreds to see the bloom, as for fully three weeks nothing could be done owing to the number of visitors who came from all parts. However, I would recommend another year that certain days in the week should be set apart for the public to see the plants. In addition Miss Woodhead has two houses full of good plants, and which are well worth an inspection.

The following are descriptions of some of the best varieties. The numbers attached to each sort are the book numbers of the parent plants. Under these numbers the plants will continue to be grown until such times as names are settled on for the varieties.

<sup>13</sup> Green edge. Tube yellow; paste fine and solid; body colour dense and black; edge deep green. Flower smooth and circular. One of the best greens in this unique collection.

<sup>8</sup> Grey edge. Golden yellow tube; paste extra fine; body colour black, evenly laid on; fine smooth edge. An immense trusser, and one of the best greys in the collection.

<sup>84</sup> White edge. Tube orange yellow; paste dense and good; body colour black and solid. A true white of the largest size. Plant of excellent habit and slightly mealed. The finest flower I ever remember to have seen.

<sup>18</sup> Dark crimson self. One of the finest tubes—rich golden yellow; paste solid and fine; edge smooth; colours finely proportioned. A grand flower.—G. RUDD.

[Mr. Rudd has sent us descriptions of thirteen green-edge flowers, eleven greys, four whites, and eight selfs. We publish one of each section as an example, and will retain the others until the varieties are named. "D., Deal," has also received some flowers from Mr. Woodhead, and has sent us descriptions of them; but it can be of slight public utility to publish them, as the flowers are necessarily under numbers, which do not indicate to our readers the parentage of the varieties. Our correspondent remarks that the flowers that have been submitted to him "give promise of valuable additions to our catalogues in years to come. The flowers are especially remarkable for their rich tubes, which are either deep yellow or orange, and a great advance on many of the newer and some of the older varieties that in this respect are defective." We may add that we have inspected Mr. Woodhead's collection of Auriculas. The plants are the finest we have ever seen, and the white-edged flower described on page 402 was the best of its class that has been brought to our notice. It is evidently the No. 84 x 4 described above by Mr. Rudd; and "D., Deal," also refers to it as a "most refined and beautiful flower." Knowing the great care that has been exercised in hybridising by Mr. Woodhead, and judging by the descriptions of the flowers sent to us, we anticipate some important additions to the "Auricula Royal" from Shibden Head.]

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 23. NEW SERIES.

WE come now to consider some singular, though not generally beautiful, species, which have furnished a puzzle to naturalists for many years past. It is all but certain that they will never agree upon the location of these species, for some declare them to be insects, some will only own them as crustaceans, and others again would form them into a separate division or class. To the ordinary observer they are insects, and so possibly they will remain, because in size and habit they appear to be so nearly akin to the insect tribes. None of them are of such dimensions as would make them conspicuous; and while some are decidedly hurtful to our plants, there are species that help to diminish the numbers of our garden enemies.

To commence with the Thysanura, which constitute the little order of the Springtails (fig. 98), thought in some things to approach the crabs, in others to resemble the lace-winged flies. The family Collembola includes species that are abundant during most seasons about hotbeds and within frames, the warmth of which appears to be agreeable to their senses. Also in the open borders, though seldom noticed there, these tiny creatures frequent succulent plants, more particularly when they are in an unhealthy condition. The presence of certain fungi has an attraction for them, and decayed roots or prostrate branches of trees which have become damp occasionally turn out to be the abiding place of myriads upon myriads of Springtails, which have had given them in some localities the appellation of "ground fleas" from their jumping propensities; but they have rather the aspect of a mite than that of a flea, the antennæ being generally con-

spienous, the legs short, the body elongated or globular, and a springing apparatus is situated at the tail. Herein they differ from fleas and various species that leap by means of the hind legs. This apparatus is closed up when out of use, and, as Sir John Lubbock remarks, it does not seem to be requisite in the case of creatures having the habits of these Collembola. Possibly the power of leaping is advantageous to them should they have to migrate suddenly in pursuit of food, but ordinarily they lie quiet, keeping more or less hidden under some substance frequented by them, or in sheltered nooks.

Nearly the largest of the species is *Smynturus fuscus*, which is about a line in length, and feeds chiefly upon fungi in their early stages, those growing upon damp bark being its especial resort. Sometimes these have been discovered in such thick swarms that

Fig. 98.—A Springtail (*Podura*, species) magnified.

they could be gathered up by spoonfuls. *S. viridis* has greenish eyes in black spots; it is common about Cucumber frames, where also two or three *Smynthuri* more are occasionally taken, but they have not been named with certainty. Curtis, in his "Farm Insects," alludes to a minute species, which was said to be injurious to the leaves of the Potato, and which was black with brownish horns. Probably it is the insect that Sir J. Lubbock separates as *S. niger*, very small and sluggish. Another species of a more lively disposition is to be detected during the winter months, *S. ornatus*; this is black, mottled with green or brown, and leaps or runs amongst dead leaves and logs of wood. As do others of the Collembola, it helps forward the decomposition of matters that fertilise the soil, and which unchanged would render the air unwholesome. All the *Smynthuri* dislike drought; also the application of salt, even in weak solution, soon kills them. Several of the insects in this group are almost colourless, and one or two species are supposed to be eyeless; also it is perceivable that though the general name of "Springtails" is given to them, some species cannot leap, but they run rapidly when alarmed. A few live under beds of seaweed partially exposed to the tide. *Lepisma saccharina*, in the small family of the Lepismidae, is very

Fig. 99.—Fish-scale (*Lepisma saccharina*) magnified.

common in some houses, manifesting a liking for sweets. It has been popularly called the "fish scale," from its body being clothed with scales. This is larger than the Collembola, being nearly a third of an inch in length, and it has a three-forked tail.

The Acarina or mites, if not true insects, certainly form a connecting link between the spiders and insects, the thorax and abdomen being closely joined, not united by a stalk, as in the spiders. In outline they resemble spiders, having eight legs when matured, but only six during their early stage of existence. It is not to be expected that gardeners should distinguish amongst species that often baffle men of science, and the place where they may occur does not always afford proof as to habit. Some, indeed, are highly injurious, but the majority occupy a neutral position, and it is not necessary to dwell upon them here. Conspicuous, however, amongst the mites that are to be found about gardens or plant houses are those that belong to the family of the Tetranychidae, called "spinning mites." Best known of these is the annoying species, familiar to us as the red spider, but in colour variable

according to the plants it frequents, being sometimes greenish or brownish, sometimes a rusty red or paler, usually semi-transparent, and lacking the velvety appearance that distinguishes another red species, not a spinner—the harvest mite. There does not seem to be any noticeable difference between the hues of the young mites and the "old stagers," except that, owing to their skin being thinner, the juveniles look more transparent, also they are less active. These have only six legs, two more being acquired when the adult stage is reached.

The thread that is spun by this mite (*T. telarius*) is so very delicate that we cannot see it without a glass, except it is woven into a web. This is spread over a leaf by the united action of the claws of a number of individuals, usually, and it secures them from being dislodged, as their foothold without the web is not very firm. Leaves are particularly attractive to them which have hairs or inequalities, about which the threads are dexterously woven. A variety of sizes may be found congregated on a single leaf, a colony perhaps of hundreds, and under their influence the vitality of the leaf gradually vanishes, and a sickly tint of yellow or grey announces its death. The influence of these mites is unfavourable, not only because they make numerous punctures in leaves and draw up the juices with their suckers, but because the pores are clogged by the fluids they excrete. Sulphur has been repeatedly proved to be of all applications the most destructive to them; soft soap and water is also fatal if it can be brought into immediate contact. The red spider has also some natural enemies, such as the grub of the lace-winged fly, which clears them off a leaf with surprising rapidity.

Hardly distinguishable from the preceding is the *T. cucumeris* of Boissduval, said to make Cucumbers and allied plants its special object of attack, though wandering from these to other plants in the kitchen garden. The economy of the Rose-haunting *T. Rosarum* is different from that of many of these mites, since it has only been detected upon unhealthy trees, the leaves of which showed a growth of fungi, such as *Uredo Rosæ*. This mite is green and slender. *T. ferrugineus* has been more observed on the Continent than in England; it is minute and very destructive to the leaves of Cyclamens. Boissduval, indeed, thinks the only remedy is to burn at once a plant seen to be infected.—J. R. S. C.

#### PROPOSED PRESENTATION TO MR. JOHN DOMINY.

IN recognition of his long and successful labours in enriching our collections of Orchidaceous plants especially, we published a portrait of Mr. Dominy in our issue of July 1st, 1880, page 11, and appended a list of the plants he has raised, with their parentage. In the following issue, on page 29, a correspondent—"DUBLINENSIS"—than whom no one is better able to form a just estimate of the merits of a fellow worker in practical and scientific horticulture, wrote as follows:—

"On opening your esteemed Journal of to-day (July 1st), I was delighted to see such a truthful likeness of Mr. John Dominy, who has for so long been the valued director of the Veitchian nursery at Chelsea. In my humble opinion you deserve the thanks of all horticulturists for having given portraits of two of the most useful gardeners of the time—I beg to use the word gardener in its best and widest sense—Robert Fortune and John Dominy; one a most successful collector, the other apart from his business tact and high cultural abilities, a man who led science by his practice as a hybridiser of Orchids and Nepenthes—the aristocracy of the horticultural world. We have had portraits of gardeners and horticulturists by the dozen, but you have struck a chord of sympathy with those of the two gentlemen I have named, both of whom have done so much in the quiet unostentatious manner so indicative of sterling merit. Poor Robert Fortune died before half the present generation of horticulturists knew his worth; fortunately we have John Dominy still with us. Shall his merit die with him unrecognised by his fellows, or will our brethren give him with their good wishes something like himself—simple, useful, and good, to remind him of the active part in the battle of life through which he has passed, and from which he has so recently retired? All that is wanted is a token of good will from those who recognise his ability or revere him as a staunch and true friend. Those who know Mr. Dominy best will be aware how far his thoughts or wishes are from desiring anything in the shape of a 'testimonial,' yet anything of a spontaneous expression of good will on the part of his compeers is welcome to any man who feels that he has done his 'level best' to deserve it. That Mr. Dominy does deserve such an expression of respect is beyond question, and I shall be most happy to add my own mite towards such an object."

From other letters we received it is evident that a disposition exists to convey to Mr. Dominy a tangible tribute of esteem; and we learn with pleasure that the question has assumed a practical form, as will be perceived by the following letter from Sir Trevor Lawrence, Bart., who writes to us as follows:—

"I am anxious to bring to notice the strong claims of Mr. Dominy

upon all lovers and cultivators of Orchids. Mr. Dominy has now retired definitively from the service of Messrs. James Veitch & Sons after being with them more than thirty-five years, carrying with him the esteem of his employers and of all who have had to do with him. I need not enlarge on Mr. Dominy's high personal character, on his industry and integrity, or on his courteous civility and attention to all. His special knowledge and skill are well known, and have been a great help, to nearly every Orchid grower in the kingdom. Mr. Dominy was the pioneer of the hybridisation of Orchids, and his skill has enriched our houses with many beautiful hybrids, such as *Calanthe Veitchii*, *Cattleya exoniensis*, *C. Devonensis*, *C. Dominiana*, *Laelia Veitchiana*, &c.

"It is not desired to do more than give Mr. Dominy a well-earned mark of the gratitude and esteem Orchid growers feel for him. Several subscriptions have already been promised, varying from £5 5s. (the maximum fixed) to 10s. 6d.; and the following gentlemen, to whom alone I have as yet applied, have promised me their co-operation—Rt. Hon. J. Chamberlain, M.P.; W. E. Brymer, Esq., M.P.; Sir Henry Peek, Bart., M.P.; Lord Rendlesham, M.P.; F. A. Philbrick, Esq., Q.C.; J. S. Bockett, Esq.; S. Lea, Esq.

"I add a list of Mr. Dominy's principal hybrid Orchids—*Calanthe Domini*, *Phaius irroratus*, *Calanthe Veitchii*, *Cattleya Brabantiae*, *C. Manglesii*, *C. quinquecolor*, *C. Pileheri*, *C. Pileheri alba*, *C. Dominiana*, *C. Devonensis*, *C. exoniensis*, *C. telix*, *Laelia Veitchiana*, *Dendrobium Domini*, *Cypripedium vexillarium*, *C. Harrisianum*, and many others."

The other hybrids alluded to will be found on the page quoted. We trust that the proposition now submitted to the horticultural public will be widely responded to, and will be conducted to a successful issue.

Subscriptions will be received by Sir Trevor Lawrence, Bart., or at the London Joint Stock Bank, Pall Mall, S.W.

### THE CARNATION.

ALTHOUGH the Carnation is one of the most beautiful and fragrant of florists' flowers, and may rank with the Rose, it does not appear to attract the attention of florists, for exhibitions of the flowers are not numerous, and in some degree this may be attributed to the attention the blooms require during the period that they become nearly in a state for staging. Daily do they need looking at, and many also require the pods being tied to prevent bursting, which would disqualify them for exhibition; and again, dressing the flowers and carding them is what few can do properly, and where there is a large number of pots much time must be spent in doing all that is requisite to procure fine blooms.

The Carnation is generally supposed to be a native of this country, and was no doubt raised from the red Clove Pink, which is found growing upon Rochester Castle, as well as on rocks and old walls where the soil is dry. According to Chaucer the Clove Gilliflower was cultivated as early as the reign of Edward III., and at that time was employed to give a spicy flavour to ale or wine. In the time of Queen Elizabeth it was in great estimation, and often celebrated by the poets of the day. Gerard enumerates forty-nine varieties that were cultivated in the time of Charles I., whose consort was extremely fond of flowers; and although many varieties were procured from France and other parts of the continent, yet the largest and principal kind of Carnation was called the old English Carnation by way of distinction. Mr. John Ray remarks in the "Flora," which he published in the year 1665, that the Dutch florists at that period had more than one hundred distinct varieties by name, all of them fair large double flowers. In a late edition of his work 360 good Carnations were enumerated by him.

In the year 1828, the period I commenced growing Carnations, the flowers were little behind what they are at the present time; but the Picotees of that time would scarcely find a place in any cottage garden now. There was not any that were edged, or rather laced, but many irregular stripes, and they continued without any improvement for many years. A variety called John's Prince Albert was the ringleader of our present varieties. It was free at seeding; and Ely, one of our greatest growers and raiser of seedlings, took advantage of it, and from it raised Field Marshal, and several small growers raised some which were an advance of those then generally grown. Nulli Secundus was raised in Yorkshire, which was the leading place in England for growers and raisers. This variety for some time took most of the first prizes, and sold at upwards of 30s. the pair. The improvement from that time became rapid, and those growers who lived when such indifferent varieties were then grown would at the present time be astonished. Mr. Charles Turner has improved the Picotees, and Mr. E. S. Dodwell has also done much in the same direction, and Mr. Simonite of Sheffield has assisted and shown some extremely fine novelties. Rose Picotees were discarded for many years, and now they have become very attractive.

Carnations are divided into three classes—Bizarres, Flakes, and Picotees. The bizarres are so named from the French word, which signifies odd or fantastical. The flowers in this class have not less than three colours arranged in irregular stripes, termed by florists ribboning. Scarlet, purple, and pink are the three colours most predominant. The two first are seldom met with in the same flower, but the two last more frequently. When the scarlet predominates and is united with a paler colour, or, as it sometimes happens, upon a white ground, it is called a scarlet bizarre, of which there are many shades and varieties; when the pink or crimson abounds it is termed a pink or crimson bizarre; and purple bizarre when the purple abounds. The crimson bizarre is so called when the pink or crimson is high and rich in colour. The flakes are distinguished as follows—Rose, scarlet, and purple flakes. Rose or pink flakes are called from the deepness or paleness of the colour; the scarlet from the stripes being a bright scarlet; and the purple from the purple stripes.

The Picotees are so called from a French word signifying pricked or spotted; but this style of marking is now superseded by a solid edging of red, purple, and rose colour instead of stripes. The rose and yellow Picotee have been much admired, and consequently have met with admirers who have devoted much time to improve them. The yellow ground ought to be much higher in colour than it generally is, and if attention is paid to it no doubt it will rank very high in the esteem of florists.

—JOHN SLATER.

### CARPET BEDDING.

HAVING been requested by some of our correspondents to submit diagrams for planting round beds on the carpeting system we publish the following, which have been supplied by Mr. Graham, who has also suggested modes of planting them effectively. It is, however, not at all necessary that the proposed

Fig. 100.

1. *Leucophyton Brownii* and a dark centre plant.
2. *Alternanthera* of any kind.
3. *Mesembryanthemum cordifolium variegatum*.
4. *Herniaria glabra*.
5. *Alternanthera amœna*.
6. *Echeveria* or *Sedum* (as previously directed).

method of planting be adhered to, as this point can best be determined by individual taste and the plants that are most readily obtainable. The present is the precise time for furnishing the beds; if done earlier such tender plants as *Alternantheras* are often injured, and are long in recovering from the check they receive at the outset. In planting the beds it is important that the plants in lines and panels be all of the same size, as the effectiveness of the beds depends to a very great extent on the care that is exercised in this respect and on accuracy in planting. Close planting is advisable for immediate effect, and thinning-out

can be done afterwards as is needful. It is not proposed to publish any other diagrams at present, as those now given, with

Fig. 101.

- 1 and 4. *Alternanthera amœna*. No. 1 with a tall centre plant.  
2. Golden Pyrethrum.  
3. *Herniaria glabra*.  
5. *Mesembryanthemum cordifolium variegatum*.  
6. *Sedum* and *Echeveria* (as before described).

others that have previously appeared from time to time, will be sufficient for affording guidance to those needing it on this mode

Fig. 102.

1. *Alternanthera amœna*.  
2. *Leucophyton Brownii* or *Antennaria tomentosa*.  
3. *Alternanthera* of any kind.  
4. Groundwork of *Herniaria glabra* or *Mesembryanthemum cordifolium variegatum*.  
5. Raised about 5 inches, and planted with *Echeveria secunda glauca* interspersed with *Sedum glaucum*.

of furnishing beds on lawns and terraces. The proposed methods of planting the beds now published appear under each diagram.

**AUSTRALIAN GRAPES.**—Mr. G. Bunyard sends the following extract from the Maidstone Journal:—"Mr. B. G. Berry, native of Faversham, has undertaken to receive from the Agricultural and

Horticultural Society of South Australia—where he lately called on a trip round the world—a consignment of Grapes by way of experiment. The South Australian Grapes are said to be the finest in the world. The various modes of packing will be tried with a view to ascertain the possibility of their reaching here in a marketable condition; if so hundreds of tons could be imported. At the time Mr. Berry was there the wholesale price was £4 per ton, or less than a halfpenny a pound for magnificent Grapes."

#### CLEMATISES IN POTS.

"How beautiful!" has been the exclamation of more than one visitor to whom I have lately been able to show a house full of Clematises in bloom. With this I could cordially agree, but it was with surprise that I heard an Orchid grower of some fame add, "Their culture in pots is not generally understood," for they are so popular and there are so many good varieties as to lead one to suppose the few and simple details of culture would have been mastered long ago. It would appear that this has not been done, and therefore Mr. Bardney's excellent notes on page 349 are calculated to do much good.

The whole of the pot plants here have been wintered for three years in an old garden frame, with earth banked up around the sides and litter thrown over the lights to exclude frost. They are repotted and retrained early in spring, when they are removed to any convenient house or pit, no fire heat being required unless very early flowers are wanted. By the end of May the flowering season of the early-blooming section is at an end, and the plants are turned out to an airy position upon a bed of coal ashes behind a north wall, where they mature their growth and remain till once more consigned to their rude but sufficiently snug winter quarters. The object of this note is to show how admirably Clematises in pots are adapted to the amateur and gardener of very limited means.—EDWARD LUCKHURST.

#### ODDS AND ENDS.

**The Fruit Prospects.**—The prospect of a fruitful year is generally good. In the south-east of England there is a fine show of fruit. Gooseberries could not be more abundant; Black and Red Currants are well set; Plums and Cherries are already swelling, the former being a particularly good crop; early Pears are swelling fast and well-set, late varieties are full of bloom; Apple trees are now very beautiful and give every prospect of a heavy crop. Wall fruits, too, promise well; Apricots, Peaches, and Nectarines, though general failures in several previous years, have the fruits the size of a good hazel nut and thickly set.

**Magnolia conspicua.**—One of the most beautiful flowering trees at this season of the year is *Magnolia conspicua* when clothed with its white and purple-tipped blooms, and is worthy of a place in every garden.

**Spiraea prunifolia flore-pleno.**—The long slender arching branches of this shrub are covered with bloom, and, like most of the double flowers, is very durable for decorative purposes. The double Cherry is of equal value for decoration, especially for the table, to forms designs on a red cloth. The wild variety of Cherry could not have flowered more abundantly than it has done this year. The different varieties of *Pyrus* are in full bloom, and are well worthy of a place in the pleasure ground. Hawthorn will this season make a wonderful show of bloom.

**Phlox subulata.**—This is a charming spring flower, now a dense carpet of its pretty pink and purple flowers. Beds occupied with it and Tulips dotted about a foot apart have a pretty effect.

**Primula cortusoides amœna.**—This *Primula* appears quite hardy, having withstood the past severe winter without being injured, and is now very beautiful, the flowers being borne well above the foliage. These *Primulas* deserve to be grown more generally than they are at present.—H. B.

**Annuals in California.**—A Croydon correspondent sends us the following. In California, a recent traveller states, "I passed yards upon yards of blue *Nemophila* in blossom in the cuttings of the railway, and saw acres of *Eschscholtzia*, making the fields yellow like our Charlock."

**Australian Pine Apples.**—Capt. Parry, in his "Voyage Round the World," says that they are the best out-of-door Pines he ever tasted, being superior to those cultivated at Madras, and still more superior to the Burmese and West Indian.—G., Brighton.

**Kerguelin's Cabbage.**—The only totally solitary vegetable of which we have a note is the Kerguelin's Cabbage (*Pringlea anti-scorbutica*). It grows about the cliffs of Kerguelin's Land and some adjoining islands far towards the South Pole. It looks like a small garden Cabbage, but often on a long trailing stalk. It is a perennial, and the flower stalks issue between the leaves from

the sides of the main stem. Mr. Moseley, who was one of the scientific staff on board the *Challenger*, says he counted twenty-eight flowering stalks of different ages on one plant in Betsy Cove at Kerguelin's Land. They appeared to belong to eight successive years.—G. J. C.

*Lomaria L'Herminieri*.—This though of moderate growth is a striking species, the young fronds being bright red, forming a good contrast with the older deep green leaves. A plant of a dozen years' growth here has a stem of 12 inches, with a head about as much through; one of *Lomaria gibba* of the same age has a stem  $2\frac{1}{2}$  feet in height and nearly 3 feet through the fronds. *L. L'Herminieri* is not readily increased, for until the plant is some age it does not afford offsets, and these when produced are from the stem, and give the plant a much finer aspect. The offsets root down the stem and require to be carefully detached. It succeeds either in a stove or greenhouse. It is seldom that a batch of plants can be obtained from spores. *L. discolor bipinnatifida*, introduced by Messrs. Veitch from Melbourne, promises to be arborescent, a young plant of three years' growth having already a short stem, from the crown of which spring numerous light green, arching, beautifully divided fronds of 18 inches or more in length, the pinnae overlapping each other, the outer subdivisions being crisped, which give it a fine wavy appearance. It succeeds either in a stove or greenhouse temperature, and is one of the most elegant and attractive of the *Lomarias*.

*Ferns on Blocks*.—Not unfrequently the common *Polypody* (*Polypodium vulgare*) is found attached to the stems of aged and decaying trees in moist shaded situations, one aged Oak that I frequently see having a very picturesque appearance from the number of plants of this growing in the angles formed by the branches, where there is an accumulation of *débris* annually added to by the advance and decay of the *Polypods*. Stumps of hardwood trees, as Oak, implanted in ferneries and clothed with Ferns that have creeping stems and ramble up or down wherever there is a moisture-holding substance to attract them, have a much more natural appearance, as may be seen at Kew, than as seen on imitation rocks, like nothing in nature or art unless it be that of a dove-cote. Blocks of Oak in a state of decay, but with heart so as to ensure their durability, will often be found in woods, and these cut into suitable lengths should have a brass screw inserted in a suitable place to secure the copper wire to for their suspension. To the surface secure the creeping stems of such plants as *Davallia bullata*, *D. dissecta*, *D. parvula*, *D. solida*, *Nipholobolus lingua*, *N. rupestris*, and *Campyloneurum caespitosum*. The *Platy-ceriums* succeed in this way, their barren fronds soon covering the blocks. A little fibrous peat may be introduced along with the plants, which may be secured with copper wire and tacks. All that is needed is to keep the blocks constantly moist, and by reversing their position they will soon be well covered.

*Marcgravia paradoxa*.—For running over rock, up damp walls, or up stumps which are kept constantly moist, this is very interesting and ornamental, the stems clinging like Ivy to the surface of the rock; the leaves—of a deep bronzy hue with a metallic lustre—lie flat on the surface, and contrast finely with the small green leaves of *Ficus repens* and its var. *minima*. It requires a stove temperature, grows freely in any moisture-holding compost, soon covering a large surface, and is readily increased by cuttings.

*Goniophlebium subauriculatum*.—For suspending this is unrivalled; its wavy fronds from 3 to 5 or 6 feet in length have a fine effect in stoves. The baskets should be lined with moss, filled with fibrous peat, and the plant introduced at the top. It requires to be kept constantly moist. *Microlepia hirta cristata* is also a good basket Fern, and so are the *Davallias*, especially *D. Mariesii*, *D. fijiensis major*, and *D. Mooreana*, care being taken to keep the compost thoroughly moist.

*Selaginella Kraussiana aurea*.—This is a golden form of the well-known green type, and like it will grow almost anywhere, increasing very rapidly, and forms a fine golden surface where there is moisture.—G. ABBEY.

*The Gooseberry Caterpillar*.—I quite agree with "K. K." (pages 418-419) with regard to keeping the Gooseberry caterpillar under. It is a cleaner and more efficient plan to take off the perforated leaves as they appear, than to allow the caterpillars to spread over the bush and then endeavour to destroy them. I search once in two days, and in half an hour can look over forty bushes.—ALPHA.

*CAMPANULA PERSICIFOLIA ALBA FL.-PLENO*.—I see by the last number of the Journal, page 421, that the Royal Horticultural Society awarded a vote of thanks to Mr. Cannell, Swanley Nurseries, Kent, for plants and blooms of this beautiful pure white double *Campanula*. I recommended through your columns a considerable time since the extended culture of this chaste and handsome flower, and think the more as time elapses that Mr.

Cannell or others cannot do their friends or patrons a greater service than by bringing it under their notice. It is perfectly hardy, but will bloom all the earlier by having a slight protection in winter, or it may be grown in a cool greenhouse, and then in spring lifted and divided; or, if you do not want to extend your stock, apply rich mulching. In the open border its fine *Camellia*-like blooms are now expanding, and there is no finer white hardy flower for bouquets.—W. J. M., *Clonmel*.

### THE GOOSEBERRY AND CURRANT FLY.

IN reference to the article and accompanying extracts, pages 418, 419, of the Journal, I wish to remark that evidently some degree of perplexity has arisen to "K. K.," and perhaps to others, from not sufficiently distinguishing between what was written upon the true caterpillar (*A. grossulariata*) and the pseudo or fly caterpillar of *Nematus* or *Tenthredo Ribesii*, decidedly on the whole the worse to deal with.

There is little excuse for anyone being troubled with the larva of *A. grossulariata* during the spring, since a proper examination of the bushes during the autumn, and precautions taken in winter as suggested, will largely assist in keeping this species down, excepting, indeed, in those cases where persons have on adjacent property bushes that are neglected by their owners.

I am sorry to see that hellebore powder is recommended by some, as to me its use during the fruiting season appears dangerous, though it might be employed in the later months of the year. A small error has crept into the account of the Currant Clear-wing. The eggs are deposited almost invariably in the month of June, not April. And in the eighteenth line from the bottom of page 419, the words "from cocoons" should have been printed "form cocoons."—YOUR ENTOMOLOGIST.

ON Friday the 3rd inst. the ROYAL HORTICULTURAL SOCIETY'S GREAT SUMMER SHOW commences, and will continue until Tuesday the 7th inst. In all the classes the prizes are of sufficient value to induce a spirited competition, and it is probable that the efforts the Council have made in augmenting many of the prizes will increase the number of exhibitors. The competition in the plant classes promises to be keen, the entries in the fruit classes are far more numerous than usual, while the display of garden structures, implements, &c., is expected to be the largest that has ever been seen in London. Stove and greenhouse plants are well provided for, three classes being devoted to them, in which the prizes range from £20 to £5. Similar provision is made for Orchids; while Azaleas, New Plants, Pelargoniums, Roses, Hardy Plants, Groups, and many others have classes devoted to them in which liberal prizes are offered. Sixteen classes are appropriated to fruits—for Pine Apples, Grapes, Peaches, Nectarines, Cherries, Strawberries, Melons, and Tomatoes, one being reserved for a collection of vegetables. Gold, silver, and bronze medals are offered for exhibits of garden structures, implements, and appliances; while special prizes are contributed by Mr. W. Bull for New Plants, Messrs. Sutton & Sons for collections of Peas and Melons, and Messrs. Boyd & Sons for a collection of Fruit. The Exhibition will be open to the public at one o'clock on Friday, and at ten o'clock on the three other days of the Show.

— THE fourth portion of MR. DAY'S ORCHIDS was sold by Mr. J. C. Stevens last week, and realised the total sum of £1521 10s. 6d. Some of the highest prices obtained were the following—*Angraecum sesquipedale*,  $12\frac{1}{2}$  guineas; *Dendrobium Brymerianum*, 20 gs.; *Odontoglossum vexillarium*, fine variety, 10 gs.; large plant, 17 gs.; *Masdevallia chimæra*, the true species, 13 gs.; *Aerides Schroderi*, 34 gs.; *Lælia anceps* var. *Dawsoniana*,

10½ gs.; *Lælia elegans* var. *Warneri*, 13½ gs.; *Vanda tricolor* var. *formosa*, fine specimen, 12 gs.; *Vanda Lowi*, 18 gs.; *Masdevallia Veitchiana* var. *major*, 19 gs.; *Cypripedium Stonei* var. *platytænium*, last plant in the collection, 130 gs.; *Odontoglossum nevadense*, 17 gs.; *Ada aurantiaca*, fine specimen, 9 gs.; *Aerides Lobbi*, 15 gs.; *Angræcum Chailluanum*, 9½ gs.; *Phalænopsis sumatrana*, 20 gs.; *Anguloa Ruckeri*, 12 gs.; *Phalænopsis tetraspis*, 14 gs.; *P. leucorrhoda*, 12 gs.; and *Cattleya Skinneri alba*, 52 gs. It is announced that the fifth portion of this remarkable collection will be sold on June 21st and 22nd. The amount obtained by these four sales exceeds £7000.

— A CORRESPONDENT sends us the following note on *CLEMATIS MONTANA*, the Mountain Virgin Bower, as it is sometimes commonly called, "is a climber well adapted for covering walls or trelliswork, and cannot be too highly recommended for covering bowers or summer-houses. It is a rapid-growing plant, and when allowed to ramble at will looks charming intermixed with Ivy and some of the larger-flowered varieties. It flowers early in the season; and the flowers, which are creamy white and slightly fragrant, are produced abundantly on the lower part of the young shoots. It is a native of the Himalayas, and is found growing abundantly at high elevations. It was introduced to this country nearly forty years ago, and, although having been in the country so many years, it is seldom met with grown as described above."

— AT the last meeting of the Royal Horticultural Society Mr. W. Brown of Hendon exhibited some plants of *CRASSULA JASMINEA*, which attracted much attention from visitors, but appeared to be known by few. It well deserves notice, for when in such fine condition as those referred to it is extremely valuable for conservatory decoration. The stems are slender, reaching the height of a foot or more, bearing narrow elliptical dark green leaves, and terminating in a cluster of from two to five flowers; these are about 1½ inch long, tubular in form, somewhat suggestive of *Jasmines*, pure white and pleasantly fragrant. The plants are grown in 48-size pots by Mr. Brown, and when neatly tied in the way of market *Mignonette* close heads of flowers are formed a foot or more in diameter. It is surprising that the plant is so little known, for it was introduced from the Cape of Good Hope early in the present century, and figured in the "Botanical Magazine." It was originally raised from seeds received by Mr. Anderson of Chelsea, and named by Haworth *Crassula jasminiflora*, subsequently altered to the one it now bears. It is referred by some authors to the genus *Kalosanthus*.

— IN the herbaceous department at Kew *CYTISUS SUPINUS* is now very attractive; it flowers freely from the previous year's growth, the long arching racemes of bright yellow blossoms being extremely handsome; the foliage has a peculiar downy appearance. The plant under notice is about 4 or 5 feet through and the same in height. It is apparently a free-growing plant, and altogether worthy of a place in any shrubbery border. It has withstood the severity of the past winter without any protection.

— WE are sorry to see the beautiful specimen of *VERONICA TRAVERSII* that grew adjacent to the above-mentioned plant at Kew has been cut down to the ground by the severe frosts of the past winter. It has withstood the frosts of 1878-1879 with impunity without any protection, but two such severe winters as the past in succession has proved fatal to many valuable trees and shrubs. It is to be regretted that this remarkably handsome *Veronica* will not stand our wet cold winters.

— MR. G. MITCHAM, The Gardens, Montpelier, London, N. sends some very fine sprays of *POLYGONATUM MULTIFLORUM*, which he says have been very much admired, as "grown in a garden surrounded with dwellings." We can quite understand

that such examples should be admired, and they show how well Solomon's Seal is adapted for town gardens. It is also very elegant as forced in pots for conservatory decoration.

— ON July the 9th an EXHIBITION OF ROSES will be held at the BRIGHTON AQUARIUM. Three classes are devoted to amateurs, but the majority are open to all competitors. The principal classes are for forty-eight varieties, three trusses of each, three prizes being offered value £5, £3, and £2. For twenty-four varieties, three trusses of each, £3, £2, and £1. A class is also provided for a group of plants to be arranged in a space of 150 square feet. The Sussex Rose-growers will have a good opportunity of trying their powers in a new field.

— VICK'S American Magazine has the following upon a CALIFORNIA RADISH—"N. H. Stedger of Sidney Kansas writes, 'In seven weeks' time last year I grew a good solid California Mammoth Radish that weighed 8½ lbs. It was also of excellent quality.'" Can growth in the electric light excel this?

— A DERBY correspondent, "C. C.," sends us the following relative to SWEET NANCY—"In this district there is no question of calling London Pride Sweet Nancy. The flower so called, whether single or double, is a *Narcissus*. The single is white, with yellowish tinge and yellow centre, and in one field is supposed to be wild, but probably it was once a cottage garden. The petals are much richer than the *Narcissus poeticus*, and the white less pure than in the garden *Narcissus*, with red and yellow centre. The double white I one day commented on to an old woman in a cottage as *Narcissus*, and her remark was, 'We call them Sweet Nancies.' Certainly the flower seems more like a Sweet Nancy than London Pride, having more individuality."

— A CORRESPONDENT, Mr. W. Morris, desires to know where he can obtain a supply of GLAZED FLOWER POTS, and the price per cast. We are unable to state where such pots are manufactured, as we do not remember to have seen them advertised. We have seen glazed pots in use, and the plants that were growing in them were in the best possible condition.

— THAT excellent variety of STRAWBERRY, PRESIDENT, is rarely exhibited in better condition than it was shown by Mr. Mortimer, gardener to Major Storer, Purley Park, at the last Reading Show. The fruits were all very even, of good size, fine conical form, and richly coloured, attracting the admiration alike of horticultural connoisseurs and the general visitors. The extreme difference, however, which cultural attention will effect in the same variety was indicated by the varying quality of the other dishes shown of President on the same occasion, for not only was there such a great diversity in form as to render some scarcely recognisable, but there was also considerable divergence in all other respects. This Strawberry seems to be a great favourite in the Reading district.

— AMONG the exhibits at the Crystal Palace on Saturday last the group of TREE MIGNONETTE from Mr. Bird, gardener to J. A. Causton, Esq., Lodgemore, West Dulwich, was especially noteworthy. The specimens were about 4 feet in height, some trained as pyramids and others with umbrella-shaped heads about 2½ feet in diameter, and a clean stem of similar height. The pyramids were even and neatly trained, the flowers being abundant and the foliage healthy. Pots 8 inches in diameter are employed, and with ordinary light soil, and the satisfactory result obtained is very creditable to the cultural skill of Mr. Bird.

— IN the pleasure grounds at Kew there is now a fine display of HYBRID AZALEAS AND RHODODENDRONS. Among the former many of the older varieties are represented, some very beautiful and unrivalled in brilliancy or diversity of tints. The Rhododendrons are chiefly confined to banks on each side of a walk extending from the ferry gate to the Sion House vista—a

portion of the gardens that is comparatively little known to visitors. Some of the finest varieties now represented are Broughtoni, catawbiense coelestinum, pulcherrimum, John Waterer, Blandyanum, Empress Eugénie, Johnsoni, Chancellor, Victoria, Macranthum, and Purpureum splendens.

— A CORRESPONDENT sends us some flowers of CHEIRANTHUS ALPINUS, and deservedly recommends it as "a hardy plant that well merits attention. It is very dwarf and compact in habit; the flowers are produced so freely, and the colour is such a pleasing shade of bright yellow, that it is invariably admired by all visitors to my garden. In addition to those characters it possesses a most agreeable and delicate fragrance, which is quite sufficient to insure its being appreciated either when growing or in a cut state. I find it well adapted for the rockery or as a marginal line to mixed borders."

— THE following GARDENING APPOINTMENTS have been recently made:—Mr. N. Coppin, late foreman at Campsall Hall, Doncaster, has been appointed gardener to Alfred G. Lucas, Esq., Cave Castle, South Cave, Yorks; Mr. John Gardner, late foreman at Coombe Abbey, Coventry, is now gardener to Lady Pollock, Hutton, Feltham; Mr. W. Bailey, late foreman at Sandbeck Park, Rotherham, is now gardener to J. Jump, Esq., Blake Hall, Ongar; Mr. Frederiek Parsons, late foreman at Hawkestone, has been appointed gardener to Mrs. Lloyd, Widberry Hill, Ware; Mr. G. Springthorpe, late foreman at Crawley Court, Winchester, becomes gardener to G. H. Palmer, Esq., Egham; Mr. Edward Wilson, late gardener to T. Farmer Hall, Esq., Effingham House, Leatherhead, has entered the service of H. M. Pollett, Esq., Highfield, Bickley, in the same capacity; and Mr. Jas. Hobbs, late foreman at Syston Park, Grantham, becomes gardener to H. B. Samuelson, Esq., Chelston Cross, Torquay.

— A DAILY paper remarks that the energy of the French character, which has astonished the world by the efforts the people have made to retrieve the disasters of the late war, is nowhere more strikingly exhibited than in the endeavours that have been made to extirpate the PHYLLOXERA. In eleven departments syndicates were formed among the Vine-growers to the number of five hundred, and by this means a joint effort was able to be made. They devoted themselves, aided by the Government, to a close inspection of all the vineyards supposed, or likely, to be affected with the Phylloxera. Sometimes remedies were applied—the sulphur treatment, and the immersion of the vineyards, so as to drown the insect pests. But the most thorough remedy was the uprooting of the infected Vines, and to do this power was given by the Legislature to override, if necessary, the objections of the Vine-growers. The Vines were dug up and burned, while the ground was disinfected to some depth. In twelve departments 130,000 acres of Vines were thus uprooted. The expenditure of the State in this work during 1880 amounted to nearly £40,000. Yet notwithstanding the devastations of the Phylloxera, the area planted with Vines is much larger now than it was before the calamity came upon them. Thus, in the Gironde, where there were 375,000 acres of vineyards, there are now 430,000 acres. Nearly 625,000 acres have been planted since the first appearance of the Phylloxera, chiefly with new plants imported from other countries, and started in soil hitherto devoted to other crops. Evidently the French mean not to lose their position and reputation as wine-growers.

#### CRYSTAL PALACE FLOWER SHOW.

MAY 28TH.

EXHIBITS were not very numerous at the first Sydenham flower show of the season, and, though several good collections of plants were staged, they were mostly similar to those exhibited at the Royal Botanic Society's Gardens on the preceding Wednesday. In few classes was there any approach to keen competition, and in some

there was but one entry, several prizes being in consequence unawarded. The most attractive portion of the Exhibition was in the centre transept, where the groups of fine-foliage and miscellaneous plants were chiefly arranged. Immediately in front of the theatre a fine bank of Clematises was notable, occupying the place of the handsome Roses in pots which Slough and Cheshunt have usually supplied on previous occasions. On each side of these were groups of Calceolarias and choice plants from Holloway; the richly coloured Crotons, handsome Palms, Tree Ferns, and other fine-foliage plants being arranged on the side stages, at the corners of which were the groups in competition. The other exhibits occupied a sloping stage in the centre of the north nave.

*Stove and Greenhouse Plants.*—In the nurserymen's class for nine specimens there were two competitors; Messrs. Peed & Son, Lower Streatham, securing the chief position with healthy well-grown plants, and Messrs. J. Peed & Son, Roupell Park, following closely with similar specimens. The most successful in the amateurs' class was Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, who staged even and handsome specimens, Acrophylum venosum, Drocophyllum gracile, and Erica Cavendishiana being especially notable for their fine condition. Mr. B. Peed, gardener to Mrs. Tredwell, St. John's Lodge, Lower Norwood, and Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, taking the second and third positions with neat examples of the ordinary plants staged in such classes.

*Azaleas.*—These were rather abundantly represented, and the majority of the specimens were in satisfactory condition as to training and floriferousness. The best nurserymen's nine were from Mr. C. Turner of Slough, all flowering well and meriting the honour accorded for them. Messrs. B. Peed & Son secured the second prize. Among the amateur exhibitors of the same number Mr. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, was a good first with handsome specimens; Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham Hill—the only other exhibitor in the class—being placed second with good pyramidal plants. In several other classes Messrs. Turner, Ratty, and B. Peed were the chief prizetakers.

*Orchids.*—There was a fair display of these plants, and the competition among the amateurs was rather spirited. In the nurserymen's class for nine specimens Mr. B. S. Williams was easily first, his collection including several of the handsome specimens previously shown at the Royal Botanic Society's Exhibition and noted in our report. Mr. Henry James, Castle Nursery, Norwood, was adjudged the second position for vigorous plants of Dendrobium nobile, D. thyrsiflorum, and Odontoglossum citrosum among others. In the amateurs' class Mr. Child staged a fine collection, for which he was awarded the premier honours; it included a handsome Vanda suavis with nine spikes of flowers, Cypripedium barbatum superbum, good, Aerides Fieldingi, and Oncidium ampliatum majus, also flowering freely. Mr. Salter, gardener to J. Southgate, Esq., Leigham Court Road, Streatham, was second, contributing fine examples of Dendrobium Dalhousianum, Oncidium concolor, and Phalaenopsis grandiflora. Mr. A. G. Catt, gardener to Walter Cobb, Esq., Silverdale Lodge, Sydenham, secured the third position with smaller but healthy plants.

*Fine-foliage Plants.*—Mr. B. S. Williams was the chief exhibitor in the nurserymen's class for nine fine-foliaged plants, and the only one in that for the same number of Ferns, securing the leading prize in both with some of the handsome specimens for which the Holloway nursery is noted. Messrs. Hooper & Co., Covent Garden, and Mr. H. James followed in the first-named class, each staging fine plants, the former especially, Palms being particularly well represented. In the corresponding amateurs' class there were only two competitors—namely, Mr. Rann and Mr. Penfold, gardener to the Rev. Canon Bridges, Beddington, who were awarded the first and second prizes in that order, the collections being very close in merit. Mr. Rann as usual carried off the chief prize for Crotons with well-grown plants bearing brightly coloured foliage. Mr. Bird, gardener to J. A. Caus-ton, Esq., Lodgemore, Alleyn Park, Dulwich, was a good second with smaller but admirably coloured plants, Mr. Penfold taking the third position. The prizes for Dracænas were awarded in precisely the same order for fresh healthy examples of good varieties. The only collection of nine Ferns was from Mr. Penfold, well-grown neat specimens, well deserving the first prize awarded for them.

Tuberous Begonias were as usual shown by Messrs. Laing & Co. of Forest Hill in excellent condition, securing the premier prize in the class devoted to them. The varieties especially noteworthy were The Hon. Mrs. Brassey, bright scarlet, large; Devonensis and Exoniensis, both good varieties, fine scarlet tint; Annie Laing, bright pink, neat flower; Lady Hume Campbell, pink, a beautiful variety; and Pollie, pale yellow. Mr. H. Coppin, Croydon, was a good second, showing several fine varieties, the best being Roi d'Or, large yellow, and Olympus, bright scarlet. Calceolarias were well represented by Messrs. Dobson & Son of Isleworth, Mr. Bird, and Mr. W. Griffin, gardener to J. Willcocks, Esq., Forest Hill. Pelargoniums were poorly shown, the only really good collection being that from Mr. C. Turner, comprising fancy varieties, which was first in that class.

*Groups.*—Four exhibitors appeared in the class for a group to occupy a space not exceeding 200 square feet. The one for which the premier prize was adjudged was staged by Messrs. John Peed and Son, and consisted chiefly of variegated Maples, standard and pyramidal Azaleas, Calceolarias, Coleuses, Palms, and Dracænas, tastefully arranged, formality being studiously avoided. Mr. J.

Salter was placed second with a valuable collection of plants, comprising many handsome Orchids and other choice plants, but there were scarcely enough foliage plants to tone the brightness. Messrs. J. Laing & Co. were third with a group chiefly composed of similar plants to those in the first-prize collection, arranged in a somewhat similar manner.

*Miscellaneous.*—Several collections of flowers and plants were contributed besides those in the classes, extra prizes being awarded to the following:—Mr. B. S. Williams for a handsome group of choice plants, including specimens of many new plants for which certificates

were awarded; Messrs. Jackman & Son, Woking, for a fine group of Clematises in pots already referred to; Mr. W. Rumsey, Waltham Cross, for four boxes of Rose blooms; Mr. H. Hooper, Bath for a collection of Pansy, Pyrethrum, and Pæony blooms; Mr. Bird for a group of well-grown standard Mignonette and Calceolarias; and to J. Willcocks, Esq., of Forest Hill, for a group of Calceolarias. Messrs. James Carter & Co., High Holborn, also contributed specimens of their Queen's Prize Mimulus, showing a great variety of rich colours.

Certificates were awarded for the following plants—

*Pelargonium Martial* (Turner).—A show variety, which was, we

Fig. 103.—RUBUS DELICIOSUS.

believe, originally raised by Mr. Bréhaut, of Jersey. The flower is of good size, substance, and excellent form. The lower petals are rounded and very bright scarlet, the upper petals being dark maroon. The truss is large, and the peculiar richness of colour in the flower renders it very striking.

*Pelargonium Mr. Henry Cox* (Turner).—A beautiful tricolor variety, with zones of colour bright and distinctly marked. This fine variety has also been certificated at several other exhibitions.

*Begonia Mrs. Robert Whyte* (Laing).—One of the tuberous section of Begonias; flower large, the petals very broad and finely rounded; colour bright pink. An extremely beautiful variety, of compact habit and very floriferous.

*Begonia Davisii flore-pleno superba* (Laing).—This handsome double

tuberous Begonia has already been referred to on several occasions, and it well maintains the good opinion formed of it when first exhibited.

Mr. B. S. Williams was accorded certificates for the following, which have been previously described—*Actiniopteris radiata australis*, *Philodendron elegans*, *Heliconia nigra punctata*, *Asplenium apicidens*, and *Odontoglossum Alexandræ* var. *giganteum*.

#### RUBUS DELICIOSUS.

ONE of the most beautiful hardy flowering shrubs is this species of *Rubus*, for which Messrs. C. Lee & Son of Hammersmith received a first-class certificate at the last meeting of the Royal

Horticultural Society. It has been long known to botanists, but has only been in cultivation about ten years, though it was originally discovered in the Rocky Mountains as early as 1822. Visitors to the Royal Gardens, Kew, have, however, for some time been annually attracted by a specimen in the herbaceous ground, where it flowers most profusely in a sheltered position near a wall. A plant is also included in the Royal Botanic Society's Garden, Regent's Park, and it is now represented in several other large public collections.

The flowers are individually of short duration, but they are produced so freely that a display is maintained for a considerable time during April or May. The petals are pure white, large, rounded and spreading, the flowers frequently exceeding 2 inches in diameter. The fruit resembles a large Blackberry, and possesses a pleasant flavour when fully ripe. This *Rubus* usually attains a height of 3 or 4 feet, at least we have not seen any exceed the latter. It is compact in habit, with rather small neatly cut leaves, and the disposition of the flowers on the young shoots imparts a very graceful appearance to the shrub when it is in good condition. The accompanying engraving faithfully represents flowering sprays from a plant grown by Messrs. C. Lee and Son at Hounslow.

#### SAWDUST FOR RHODODENDRONS.

WHEN I was at Mentone, about six weeks since, Dr. Bennet showed me some Rhododendrons, as a curiosity, growing in his garden in the Maritime Alps. He informed me that the peat in which they were growing had cost him £20 to obtain by rail from, I think he said, Milan. I gave him the description of the Rhododendrons in the garden of the late Mr. Cuthbert Johnson at Croydon, growing entirely in sawdust. It must have been fifteen or sixteen years since I first saw this experiment. The Rhododendrons were then growing luxuriantly in a large bed of pure sawdust. As I was interested in this mode I again called ten years afterwards, and Mr. Johnson again showed me the result. He said, "You see on the right that large bed of Rhododendrons with leaves growing with great vigour, but there is not a single flower; on the left you see the plants covered with flowers, and of a large size. Those on the right are growing in oak sawdust; those on the left in deal sawdust." If I am not right I must be corrected by the Editor of this Journal, who is well acquainted with these experiments. Turpentine might probably be so prepared as to prove a valuable manure in the formation of the flowers of many plants. Dr. Bennet said he should immediately profit by my information, as there was an abundance of deal sawdust in Mentone.—PHILODENDRON.

#### KITCHEN GARDEN.

THE latest sowing of main and late crop Peas must not longer be delayed, any sown after this should be early varieties. The weather recently has been so dry as to necessitate watering and mulching rows of early Peas. The latter prevents evaporation and heavy soil from cracking. If Broad Beans are required very late a sowing may be made of the Longpod varieties, Monarch being suitable. If requisite another sowing of Runner Beans should be made. Make another sowing of Dwarf Kidney or French Beans, giving preference to such varieties as Canadian Wonder, Liver-coloured, and the Negro-Longpod. Root crops, indeed all crops, are much later than usual, but attention must be given to thinning before the plants become large and crowded. Button Onions are generally wanted in large quantities; the thinnings of Onions replanted thickly into drills will give the requisite supply of such without interfering with the supply of spring Onions. In thinning Carrots many more should be left than will ultimately be required, so as to allow of every alternate one being drawn in a young state. Parsnips should be finally thinned to 9 inches or 12 inches apart; Chicory and Beet to a similar distance. Salsafy and Scorzonera may be left 6 inches asunder, and Leeks in beds the same distance, every alternate one being drawn in a young state for soups. Early-sown Leeks which are large enough for planting may, where they are wanted of a

large size, be placed in trenches prepared as for Celery, and be well supplied with water and liquid manure in dry weather. Celery plants in an advanced state should be placed in trenches, single rows being preferable, except for the early crops. In the preparation of the trenches a plentiful supply of decayed manure is requisite, which should be dug-in when moist. Late-sown plants can be pricked off in prepared beds of rich compost, shaded until established, and well supplied with water. Advanced crops of Cauliflowers, Brussels Sprouts, and Savoys may be planted out as ground becomes vacant. See that there is not any neglect in sowing Spinach, Radishes, Lettuce, and Turnips, also make frequent sowings of Mustard and Cress. Tender herbs such as Sweet Basil, Sweet Marjoram, Summer Savory if gradually prepared may be planted on warm borders, and Capsicums in a row about a foot from the base of a south wall. Vegetable Marrows require a sheltered position fully exposed to the sun, where plentiful supplies of water can readily be given in dry weather. If handglasses can be afforded for a short period it will be an advantage. Ridge and Gherkin Cucumbers should have similar treatment. At all seasonable times keep the surface soil well stirred about all growing crops. Well ventilate frames containing late crops of French Beans.

*Tomatoes.*—Plants of these that have been well hardened off may be planted against walls. Take out the soil and fill up with a compost of two parts strong loam and one part decomposed manure, mulching with 2 or 3 inches thickness of the latter, and well supply the plants with water. Train with one stem and remove all laterals. In a favourable season Tomatoes do fairly well in the open in rows 3 feet apart, and the plants about 30 inches asunder, securing the growths as they advance to stakes about 3 feet above ground. In the southern and midland counties the earliest fruits ripen moderately well, and the small fruits are cut in autumn and ripened in glass structures. The fruit under such conditions does not attain the colour and flavour of that ripened under more favourable conditions. The chief supply should whenever practicable be obtained under glass, yet that grown outdoors is found a useful auxiliary.

#### FRUIT HOUSES.

*Vines.*—Thinning late Grapes should not be delayed, as they swell so rapidly at this season that they soon become too large to be thinned expeditiously. Those Vines that were not started early will only now be in flower and must have every attention. Varieties that do not set their fruit well, such as Lady Downe's, West's St. Peter's, &c., should have a constant circulation of dry warm air, and a temperature of 80° to 85° by day, and 70° at night. When watering is necessary let it be done thoroughly. To crops in the process of swelling off a little guano sprinkled over the surface of the border previous to watering will be beneficial, and a mulching of short manure after a good watering will help to keep the border moist and lessen the necessity for its repetition. Maintain a sweet atmosphere in all houses where fruit is swelling; and although fires cannot be dispensed with at night, much may be done to economise fuel by closing the house early with plenty of moisture on fine afternoons. Where Grapes are ripening a constant circulation of air must be secured, otherwise good colour and finish can hardly be expected. Early Vines which have been cleared of fruit should be copiously syringed with tepid water to cleanse the foliage of dust and red spider; and if the foliage is good keep the laterals in check by pinching, but if the Vines are weak allow a moderate extension. Do not neglect the borders, but keep them moist and mulched so as to secure the proper development of the fruiting buds for next season. Muscats completing the stoning process must be watched in bright weather, and if scalding of the berries commences admit air abundantly for a fortnight, when all danger will be past. In houses where the Grapes are ripe keep the Vines free from lateral growths, and the atmosphere as cool and as dry as is consistent with the maintenance of the foliage in good condition. Vines in pots should have the leading shoots stopped when about 8 feet long, and have the laterals and sub-laterals pinched at one joint as produced, especially those intended for fruiting next season.

*Cucumbers.*—This may be said to be the height of the season alike for a good supply of fruit and for red spider with other insect pests.

Bountiful supplies of liquid manure will be required about twice a week, and atmospheric moisture must be provided freely, especially in hot weather. Shading should not be resorted to more than is necessary to prevent flagging. Training, stopping, and thinning out the foliage and exhausted growths must be regularly attended to. Do not overcrop nor allow the fruit to hang too long, for nothing, except seeding, has such a weakening effect on the plants. If seed be wanted the present is a good time to fertilise some of the flowers, selecting the most promising. Utilise pits and frames directly they become cleared, observing the conditions previously advised. Fumigate moderately directly green fly appears. Keep the evaporation troughs charged with guano water, and sprinkle available surfaces with the same at closing time.

**Melons.**—Afford support to fruits which are becoming heavy. Keep a vigilant watch for cracked fruits, cutting the stems about three parts through below the fruit. For canker rub quicklime into the affected parts. Fertilise the pistillate blossoms on successional plants every day, maintaining a drier atmosphere and somewhat higher temperature till the fruits begin swelling, and be careful not to allow one or two fruits to take the lead of the others. Earth up, using good loam, pressing it down well, directly the fruits begin swelling, having previously soaked the soil with tepid water. Afford tepid liquid manure to plants bearing fruits, syringing moderately on fine afternoons. In pits and frames let the fruits in a forward state be well exposed to the sun. Sow as occasion requires for succession.

#### GREENHOUSE.

Examine Pelargoniums not yet in flower, for if aphides are allowed to remain fumigation will be necessary after the flowers are expanded, which will cause them to fall in quantity. Assist plants that are flowering, with liquid manure. Fuchsias also should be well supplied with water and be syringed every afternoon, so as to keep down red spider. Primulas intended for autumn flowering should be potted off singly, returned to gentle heat until established, and then be transferred to cold frames, ventilating freely and shading from bright sun. Transfer the plants into larger pots as required, and remove all trusses of bloom until September. Cinerarias for autumn flowering should have similar treatment. Chrysanthemums should now receive their final potting; good turfy loam with a sprinkling of sand suiting them well, employing crushed bones in lieu of crocks for drainage. Stand the pots on ashes in a sheltered situation, yet having plenty of sun, and after the roots have taken possession of the fresh compost liquid manure may be given.

**Heaths.**—Remove the decayed flowers from these plants. More water will be required shortly than at any other time, the safest plan being to examine the stock morning and evening and afford supplies of water to such as are in need. Any plants of *Erica Austiniana*, *E. Irbyana*, *E. Marnockiana*, *E. Jacksoni*, and *E. retorta* major required for August and September flowering should now be attended to, placing them in a house with a north aspect, where they can be well exposed to light.

**Camellias.**—Those that flowered early and were at once placed in heat will by this time have set their flower buds. The buds in some cases having attained a considerable size, the plants should be removed when the buds are the size of large Peas to a house with a north aspect. If the buds swell here too rapidly they may be placed behind a north wall with a temporary covering of loose lights. Camellias ought not, if it can be helped, be placed out fully exposed; for although they require plentiful supplies of water during growth, they become so soaked by heavy rains when in the open air after their growth is completed as to cause the loss of the roots, also causing the buds to fall later on. Plants that flowered late will, if the pots are filled with roots, be benefited by the application of clear liquid manure until the buds are set.

**Azaleas.**—Plants that flowered some time back will now be growing, and any that require more root room must now be repotted, but it is not advisable to shift them before some growth has been made, as they do not root freely. Employ good fibrous peat with enough sand to keep the soil open, and make the fresh soil as firm as the old ball; shade for a few days after potting, keeping the house close and moist.

Hardwooded plants as they cease flowering must immediately have the seed pods removed, as nothing taxes the energies of the plant so much as the formation of seed. *Eriostemons*, *Epacris*, *Acrophyllums*, and similar plants are much injured if this be neglected. Syringe freely to cleanse the plants. *Cytisuses*, *Acacias*, &c., should be cut back to keep them in form, and any others that are becoming straggling should be cut in as soon as the flowering is over. Syringing in the afternoon will be necessary to keep down red spider.

#### FLOWER GARDEN.

The favourable change in the weather has given an impetus to bedding-out, which is often done in too much haste, the plants, from the cold state of the soil, not progressing for some time after planting. Nothing is gained by being in too great a hurry, for unless the weather is genial and the plants well prepared by hardening off they are greatly checked. *Calceolarias*, *Verbenas*, *Pyrethrums*, *Echeverias*, *Gnaphaliums*, *Petunias*, and the hardier *Pelargoniums* may be planted out ten days or a fortnight in advance of *Coleuses*, *Iresines*, *Alternantheras*, *Tricolor Pelargoniums*, and subtropical plants, which should not be planted until the early part of June; but to facilitate the work all arrangements should be completed at once. In the absence of rain plenty of water should be given to settle the soil about the roots. *Asters*, *Stocks*, *Zinnias*, *Phlox Drummondii*, *Scabious*, *Marigolds*, and other half-hardy annuals should now be planted out, selecting if possible a dull day for the operation, and dust well with quicklime or soot. Hardy annuals should be thinned when they are large enough, allowing space for the development of the plants. For a late display of bloom make another sowing of these. *Roses* are not growing freely, and are becoming infested with aphides and the leaf-rolling caterpillars. Remove the latter by hand, and to destroy the aphides wash well with tobacco water. Climbing and other *Roses* against walls should in dry weather have copious supplies of water or liquid manure.

#### SECURING STRAY OR WILD COLONIES OF BEES.

A REQUEST from a correspondent for advice relative to the best means of capturing a nest of bees which has for some years lived, swarmed, and thriven in a roof, induces me to give a short account of a couple of expeditions in which I have taken part, and which had for their object the restoration to civilised courses of bees that had hoped to free themselves from the trammels of bar-frames, the dull uniformity of foundation combs, and the innovation of section boxes by hiding away to the seclusion of a double brick wall in one case and the height of a church roof in the other. The story of how combs, workers, and queen were charmed into the hive will answer our correspondent, and make clear the simple device by which colonies in inconvenient places may be dislodged and made to enrich the apiaries of their captors.

The double wall formed part of an old structure, and through an aperture, the result of decay, the swarm had evidently entered, and had utilised, as we afterwards found, an interspace only  $4\frac{1}{2}$  inches wide from front to back. A bricklayer was employed to cut out the front bricks, to lay the colony open to view, and this work acted like the hive-beating in driving, completely quieting the bees, which made no resistance to the removal of their comb. The bricklayer was not a bee-keeper, and so it soon became expedient to remove the bricks myself, lifting out the honeycombs as it was possible to free them. These I found about 3 feet 6 inches deep, and supported at intervals by cross bricks, but unfortunately as we came upon the brood combs the queen with the greater number of bees retreated into the recess beyond reach. All the brood combs by cutting, trimming, and fixing into frames were made ready for the hive, but the inhabitants, except the very young, flew from them and returned to the wall. The queen was not with us, while nearly all the bees were with her, and quite inaccessible, unless so much of the wall was to be removed as to endanger its safety. In this dilemma we fixed the frames with their brood combs as nearly as possible in true position, and in the spot the brood had previously occupied, nailing up over all a large gardener's mat.

So soon as quietude was restored the bees with their queen

returned to feed and warm their young. The next morning the mat was lifted with as little disturbance as possible. The insects were discovered closely clustered, putting their plundered house in order. The hive to receive them stood against the wall just under their old entrance. Frame after frame was lifted down, the queen in due course making her descent with the rest. The few bees that took wing soon learnt the position of their comrades, and the colony was established in its new quarters with but very little loss, and yielded its owner a fine super at the close of the summer. The main point of interest rests in the manner of capturing the queen by restoring for a time the combs, to which she will infallibly return, when their second removal is too rapidly and quietly accomplished to give her an opportunity of eluding us.

But to our second case. The three or four colonies in the roof of Much Hadam Church, the descendants doubtless of one, had behaved so badly that further forbearance was impossible. A swarm was sent out on the morning of a confirmation, and, audaciously entering the church window, clustered on an ornament not far from the pulpit, and one reckless bee from this cluster committed the sad indiscretion of stinging a bishop. This sealed their doom, and not long after ladders were raised, and your humble servant was peering down between the slates as the saucy insects were travelling in and out through four or five openings. The master builder in attendance came to give directions, but a gust of wind, common at such altitudes, nearly carried away his hat. His rapid movements in preventing this catastrophe produced a worse, for five or six bees, which regarded this quickness as a menace, took aim at his uncovered scalp and caused him to retire discomfited. A practical breach was soon made, and then painful after painful of honeycomb, which at length fairly filled a large saucer bath, was the first instalment of the booty. The brood combs followed; but as before, the bees retired and had to be gained by the expedient previously explained. While the queen and retinue were returning to their old quarters, so as to make their final dislodgment easy, the extractor was set to work upon the comb honey, and soon 60 lbs. of splendid honey was freed from wax and pollen. After the final removal of the bees the following morning, the hollow in which this colony had existed for several years was, by my order, filled with coke previously saturated in carbolic acid. This last substance emits an odour so disgusting to the genus *Apis*, that no fresh swarm is likely to choose this spot as a dwelling place. The other families, now the way had been shown, fared no better than the others, and a volunteer clad in armour for the occasion at a point where more climbing ability than I possessed was required, attacked, defeated, and captured a colony without receiving damage, while his clothing grew so sweet and sticky that now a few of the enemy became attached to him. —FRANK R. CHESHIRE, *Avenue House, Acton, W.*

#### QUEEN REARING FROM NUCLEI.

ACCORDING to instructions in your calendar for May, on the 14th inst. I took two combs out of my best stock containing eggs and larvæ, and put them into a snug hive on a new stand. I put two other combs with honey and hatching bees, and shook more bees as well to keep thoroughly warm. In two days I looked in, but no queen cells were begun. In two more days (17th my diary says) nucleus all right, but no queen cells begun. Thinking the eggs were too old, I gave another frame of very small eggs on the 19th, still no queen cells. I then gave a comb with one queen cell from another hive, which I did not want to swarm. On the 20th I found two small queen cells begun on the comb given on the 17th. On the 25th I put in two large queen cells from a third hive. These I have not since examined; but, to make a long story short, I cannot make out why this nucleus did not do as yours do, and build queen cells right off. —W. P. EDWARDS.

[You have misunderstood our instructions. We do not make nuclei in order that the bees in the nuclei may raise our queen cells, but in order that they may receive and hatch queen cells built in a strong stock in some way made queenless. Our words are these, "We select our best colony, the bees of which present the characteristics we most value, and remove its queen in some manner that does not seriously thin the population, in order that it may produce a number of highly nourished young queens." We then fully explain how the nuclei may be made "the day before the queen cells are ready for excision." The nucleus in your case acted naturally enough, for it required time to ascertain its orphan condition, but no doubt the queen cells were already in progress before you noticed them. Had the little lot of bees possessed newly laid eggs at the time you separated them from the main body they might have delayed moving in the matter of queen-rearing to the seventh day at least, and yet have produced

from their youngest grubs fairly good queens. It is the habit of weak lots to delay in this matter, and to produce but very few royal cells. The stock referred to in the calendar furnished us with twenty at least, and some of the queens raised therefrom mated in the bright sunshine of Saturday last. The smallness of the queen cells referred to might have been actual, although queen cells do not show their size until sealed. The best queens are undoubtedly raised amidst a thronging host of workers, and not amongst the starvelings of a nucleus, although there may be abundantly sufficient to brood the sealed cell and give a home to the young queen until a more worthy throne is vacant to receive her.]

BRITISH BEE-KEEPERS' ASSOCIATION.—Some time ago it was stated in the newspapers that there would be an exhibition of bees, &c., in connection with the Royal Show at Derby in July next. Will you kindly inform me through the Journal, 1, Has any prize list for bees yet been issued, and if so where can I obtain one? 2, What date the entries close for honey, &c.? If they wish, as they state, all concerned to compete, why is it not better advertised? —C. Z. H.

[We have received a prize list of the Show to be held at South Kensington, but not of the Derby Exhibition. We are unable to answer your other questions. The Assistant Secretary, Mr. J. Huckle, King's Langley, will no doubt supply the information if you write to him.]

#### TRADE CATALOGUES RECEIVED.

George Gummow, Loughborough Road, Brixton.—*Catalogue of Bedding Plants.*

James Carter & Co., 237, High Holborn, London, and Forest Hill, Sydenham.—*Catalogue of New and Choice Plants.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (*R. J. J.*).—Some works on bulb culture have been written by Mr. D. T. Fish, which would probably suit you. You can obtain particulars as to price, &c., either from the author at Hardwicke Hall, Bury St. Edmunds, or the publisher, 170, Strand, London. Your second question is too indefinite. Some books are very costly, others very cheap; some refer to stove plants, Orchids, &c., others to hardy flowers. If you will state your wants more fully and clearly we will endeavour to aid you.

Intermediate Stock (*G. Mitcham*).—The plant you have sent represents a very good variety, being dwarf and sturdy in habit with large double flowers of rich colour. Although we have seen Stocks quite equal to it, and occasionally deeper in colour, yet you are quite justified in endeavouring to keep the strain distinct, as it is superior to the ordinary forms of Stocks that we often see flowering at this season of the year. Your Solomon's Seal is noticed on another page.

Rocamboles (*Gardener*).—*Allium Scorodoprasum* is the Rocambole of the botanists, and the plant is a native of Denmark, but now naturalised in this country. The Tree Onion, *Allium Cepa bulbiferum*, is commonly known as the Rocambole of gardens; the bulbs grow in a cluster on the top of the stems, and are used the same as Shallots. The Potato Onion is *Allium Cepa aggregatum*, the bulbs forming in clusters partly in the ground and partly above it. We have grown both the Tree and Potato Onion, the culture being the same as required by Shallots and Garlic.

Zonal Pelargonium (*J. W. M.*).—Every petal had fallen from the truss of the Zonal Pelargonium, as they usually do when the flowers are not gummed. Varieties of florists' flowers are far too numerous and too nearly alike to permit us to undertake the naming of examples that are submitted to us; still we readily give the names of any flowers that we can recognise. From what you say of your variety we do not think it improbable that it is an unnamed seedling.

Insects on Peach Tree (*Alpha*).—The variety you name is not more liable to be attacked with insects than other Peaches and Nectarines are. Your trees and wall require a thorough cleansing during the winter, and then timely measures should be taken for preventing the insects appearing in the spring. When once they are established they are difficult to destroy. Nicotine

soap is a good remedy, but the insects are not easy to reach when closely enveloped in the curled leaves.

**Greenhouse Plants** (*Kittie*).—As a rule plants thrive much better during summer on a slate or other stage covered with cocoa-nut fibre refuse than on open latticework. If the fibre is kept moist in hot weather it is of great advantage to all the plants you name. During winter it may be necessary to place the Pelargoniums and Coleuses on inverted pots, and the fibre should not be so moist at that time as in summer.

**Camellias and Azaleas** (*Old Subscriber*).—The temperature of a vinery is precisely suitable at this period of the year for the plants after they have ceased flowering, and the shade of the Vines is beneficial to them. They should be syringed regularly twice a day, and the atmosphere be kept in a genial condition. Your views on the management of the plants are quite right; heat, moisture, and moderate shade are essential for promoting healthy growth.

**Gishurstine** (*W. T.*).—As you will see from an advertisement in the front page of this Journal this useful compound can be had from most seedsmen and oilmen. Those who do not have it in stock will doubtless procure it for you if you request them to do so.

**Striking Double Wallflowers** (*M. E. H.*).—Cuttings of young shoots inserted now in sand under a bellglass and placed in a heated frame or propagating house strike as readily as Fuchsias and Verbenas do that are treated in the same manner. If the Wallflowers have to be struck under handlights, or even in a shaded border, short stubby side shoots a little hard at the base and slipped, not cut, off the stems emit roots more readily than the more tender shoots do. Suitable slips can generally be had from the middle of June to the middle of July, according to the condition of the plants and the position where they are grown.

**Cucumbers Unhealthy** (*Mrs. Finch*).—We fear from your description that the young Cucumbers are attacked by the disease, and if so, it is almost if not quite impossible to rid them of it and render the plants healthy. We could better have answered your inquiry had you sent us a portion of the unhealthy plants. You do not state the temperature in which your plants are grown, nor the general treatment which they receive, so that it is impossible to state whether you are right or wrong on those points. The plants, however, we think are in too rich soil and cannot elaborate the abundant sap with which they are supplied.

**Woodlice** (*H. Hoskins*).—You may entrap many of them by placing a cold boiled potato in a flower pot and covering it with moss. If the woodlice are numerous they will be attracted by the bait and can then be destroyed. If several pots are employed and regularly examined every morning you may soon reduce the troublesome and destructive pest. We do not know what you mean by your question on variegated Carnations, for the flowers of nearly all of them are variegated or parti-coloured. Do you mean that the foliage is variegated?

**The Sawfly** (*Alpha*).—The name Sawfly is applied to several distinct species of insects that possess a saw-like apparatus, with which they puncture the surface of the vegetables selected as a nidus for the eggs. Referring to the Turnip and Gooscherry fly the Rev. J. G. Wood thus describes this peculiarity—"If the reader will catch either of the above-named insects, and will look at the under side of the abdomen, he will perceive a longitudinal notched ridge extending to the end of the body; then let him take a fine needle, insert its point under this ridge and raise it, when he will find by the aid of a magnifying glass that he has brought to view the singular double saw from which the insect derives its name, and which rests between two horny plates acting as a sheath. The shape of the saw varies much in different species, but they all agree in having a delicate blade, with obliquely-cut teeth, and a thickened back, which enables them to play freely in the groove which directs their progress." It may be further added that these saws are side by side, and work alternately, while some species have a secretion which accompanies the egg, and secures it in the place prepared for it.

**Literary Hash** (*G. R.*).—We have read the two articles to which you direct our attention, and there appears ground for supposing that the one that last appeared is, as you say, a "hash up" from a communication of your own that appeared in another paper. We fear there is much that passes as original now-a-days which is mere "hash," but veiled with more or less ingenuity by the cookers of articles for the public. Editors are occasionally imposed on in this respect, and they ought never to admit further communications from a writer who has been found guilty of these disreputable pilfering practices. You had better point out the circumstance to the two editors, who will be obliged to you for directing their attention to what must have escaped their notice.

**Carpet Beds** (*Inquirer*).—As you do not ask for any precise information we fail to see how we can assist you. Many designs have been published in the back numbers of the Journal, and two in recent numbers that are suitable for your beds; if the latter are too intricate you can have back numbers, price 3½d. each, containing simpler diagrams. The mode of planting is usually governed to a great extent by the plants at disposal. If you send 1s. 2d. to the publisher and ask him to send you Nos. 703, 704, 705, and 706 you will find seven plans, any of which are suitable for your oblong beds, and some of them are very easy to plant. From these you can select the designs that are best adapted to your purpose. Some designs for round beds appear in the present issue, and we can send you back numbers with other diagrams for round beds at the price above quoted if you need them. This reply will also suffice for "W. C."

**Beetle on Asparagus** (*W. H. M.*).—Your plants are attacked with the Asparagus beetle, *Crioceris asparagi*. Miss Ormerod, in one of her reports on injurious insects, states that in her garden near Isleworth she stopped what was becoming a destructive attack by syringing the plants with warm water, just hearable to the hand; this sent off the larvæ, or loosened them so as to fall to a shake; and throwing soot liberally through the damp shoots to the ground destroyed the fallen grubs. This treatment repeated once or twice in the course of the season completely saved the plants, and the soot gave a luxuriant and healthy growth.

**Strawberries not Flowering** (*Saxoring*).—If the runners that were planted early last year were taken from a fruitful stock in all probability the plants will produce flowers next year, and we should certainly give them a trial; but if they were taken from barren plants we should have doubts of the new plantation proving satisfactory. We have known plants similar to yours that eventually became productive. Remove the runners as they appear, and keep the ground free from weeds so that the sun and air have access to the crowns, and the plants will assume a fruitful character. We have known young Strawberry plants barren the first year solely through having been planted too deep, and we have also known the fruitfulness of plantations impaired by the overcrowding of the crowns, or what should have been crowns, by growth and weeds.

**Planting Tea Roses** (*J. E.*).—In all probability the best plan you can adopt will be to plant out the Roses, and they will probably do well in your rather strong soil, especially if you can place a handful or two of lighter soil round the roots to give them a start. A very sunny position should not be chosen, shade from the mid-day sun being beneficial to Tea Roses, but it must not be the shade of overhanging trees. The plants usually grow well in a border on the north side of a wall during the summer. If the position is sunny the surface of the soil should be mulched with manure, and the growths must be kept free from insects and mildew. If you will send us your name and address we will write to the gardener to whom you refer on the question you have submitted; you can also at the same time send the price of the volumes in case we may have an inquiry for them.

**Layering Carnations** (*Idem*).—Layering may be done as soon as the growths are long enough to be tongued and pegged down without breaking, their points at the same time pointing upwards. Layers are usually ready when the plants are flowering, and the short tender shoots are not suitable. When a shoot is selected for layering all the leaves should be removed from the base to where the tongue is to be made, which is usually 4 or 5 inches from the terminal point. There are two methods of making the tongue. 1, With a very thin and sharp knife commence cutting on the under side of a shoot, drawing the knife upwards through the joint above as if splitting the stem; 2, pushing a very small and sharp penknife quite through the stem above the joint where the tongue is needed, the edge of the knife being downwards, then swiftly draw the knife down and out on the under side, and a tongue is the result. These tongues must be kept open and pegged into sandy soil, which must be kept constantly moist. You had better practise on a few growths of common varieties at first, and a few of these you will probably either cut or break off, and thus you will learn how to apply the knife and use your fingers and pegs in the operation.

**Peach Leaves Scorched** (*T. S.*).—The immediate cause of the injury to the foliage is scorching, but there may possibly be a more remote cause that has led to the evil. If you carefully examine the injured leaves, which at the first glance appear as if they had been eaten by an insect, you will find first a dark discoloration, then a shrinkage of those parts where the tissue has been ruptured, and which eventually separates from the healthy portions of the leaves, and thus form holes and fissures. If the roots of the tree were healthy and active and could obtain the requisite moisture for the support of the growth, the evaporation would not have been so disproportionate with the supply of sap, and the withering would not have occurred provided there was no fault in the glass that led to scorching. As a remedy we should first shade the tree, either by sprinkling limewash on the glass or covering with tiffany, and syringe judiciously to keep the foliage fresh, then examine the roots and rectify any mistake that you may find there. The border may be too dry at the bottom, or the soil not sufficiently fertile, needing liquid manure, or the roots may have come in contact with something that has injured them. Examine also the stock of the tree, which may not be healthy, or the sap vessels may be too contracted. By some cause or other the supply of sap is insufficient, the sun extracting the moisture from the foliage faster than it is supplied by the roots. A close examination founded on these suggestions will probably lead to the discovery of the real cause of injury, and a remedy will possibly be dictated by the circumstances of the case.

**Seedling Calceolaria and Tropæolum** (*F. Squire*).—Two leaves of a Tropæolum are totally insufficient for anyone to form an estimate on either the merits of the plant or any special features that it is supposed to possess. A spray with flowers ought to have been sent. There are some varieties of Tropæolum of slender growth, but the size of the foliage depends to a very great extent on the soil and position where the plants are grown; for instance, those grown in pots nearly always have smaller foliage than others of the same variety that are grown in the rich soil of an open border. The Calceolaria flowers were completely withered, the result of packing them in dry cotton wool instead of damp moss and soft green leaves of any sort, Spinach being good for this purpose. Although we have repeatedly referred to the unsuitability of dry wadding or cotton wool for placing round flowers, we received more flowers packed in that substance than any other, and nearly all that are of a fragile nature are destroyed. Your Calceolaria we can perceive has the upper lip more developed than usual, and the flower is of good colour and densely spotted, but whether it is of good form or not it is impossible to tell from the shrivelled examples before us. We have occasionally seen flowers having the upper lip as large as the lower, but yours is not so, and we do not think it is particularly novel.

**Syringing Vines** (*J. T. S.*).—We could name several gardeners who grow excellent Grapes without syringing the Vines, and others who grow them equally well yet use the syringe daily. We have grown Grapes for a number of years without syringing, and the crops were such as satisfied us and other competent judges who saw them, both as growing on the Vines and as honoured at exhibitions. When the Vines are quite free from insects, and the atmosphere of the house is well managed, and especially if care is exercised in the simple matter of sweeping floors and stages in the house so as not to raise one particle of dust, we do not consider that syringing as a system is necessary; but we have found the advantage of giving the Vines a few thorough washings during the season by directing the syringe between the bunches, and applying the water with some force to the foliage, and also with a greater force to the glass above it, so as to fall down in a volume and wash the upper surfaces of the leaves. This we have always found beneficial; but the work needs to be done with care, as a clumsy workman might wash half the bloom from the Grapes, while a competent one would not remove a particle. Some water, too, is quite unfit for syringing purposes, and leaves a sediment on the leaves that is injurious. Again, some water that is safe is improperly applied; we mean that one man might use it with impunity to the Vines, while another would impair the value of the fruit. We know of some good gardeners who object to systematic syringing, but who reside in districts where the soil is light and sandy, and there feel obliged to syringe in consequence of the great prevalence of red spider; in other districts the same gardeners would not syringe the Vines. Without knowing the condition of your Vines and the general treatment to which they are subjected, and not being acquainted with the nature of the soil and climatal condition of your district, we are not in a position to decide the point you submit; but this we will say, that if the Vines were ours and quite clean, and red spider does not usually abound on the Kidney Beans in the garden during the summer, we should try and grow good Grapes without syringing regularly, and should expect to succeed in our object.

**Stopping Melons** (*C. C., Donegal*).—We do not know what you mean by the "crown." The term is not employed either in the article to which you refer nor in the manual you quote. There is a slight difference in the two articles, but no contradiction, and both are quite sound. There is more than one road to London, and travellers by steadily pursuing the road they choose, if it is a

right road, arrive at their destination; and if you follow strictly, or as strictly as your circumstances allow, the instructions in question, you will in due time have Melons. For the sake, however, of precision, we advise you to follow those given in the Journal of March 17th. The main shoot of a Melon plant, if it is stopped when it nearly reaches across the frame, will produce fruit-bearing laterals. The growths should be stopped at one leaf beyond the fruit, or if space is plentiful two leaves may be allowed, but one is sufficient. After a sufficient number of fruits are set all the growths should be stopped as they appear, retaining only the principal foliage, which must be kept clean and healthy, and be neither crushed, scorched, nor infested with insects. Until you secure a sufficient number of fruits permit the laterals to extend from any portions of the plants that show fruit, stopping, as we have said, one joint beyond each, continuing the pinching as the growths are produced. When the requisite number of fruits are swelling permit no laterals to extend from anywhere, but direct the whole strength of the plants to the principal foliage and fruit. This, on the point of stopping, makes the matter clear to you. Now to pruning. If you have much growth that needs removal, remove it gradually, a portion on one day and the remainder on the next and succeeding days; but the true course is to prevent overcrowding by a systematic pinching of these young shoots that are not wanted as soon as they appear. It is important that the fruits required for the crop be as nearly as possible of the same size. If there is a great difference between them the smaller are liable to cease swelling and be worthless. There is nothing to choose between the two methods of fertilisation to which you refer; so long as the pollen is conveyed to the pistil of the fertile flower it does not matter how it is done. If we have not made the subject clear, we are quite willing to aid you further if you make your precise wants known to us.

**Stopping Vines (*Idem*).**—The laterals should be stopped at one or two leaves (according as there is space for the foliage to develop) beyond the bunches before the period of flowering, and then again after the berries are set, continuing the practice as long as growths are produced. We do not advise stopping the growths when the Vines are in flower, nor is there any necessity for this if the laterals have been properly attended to. Red spider is a very small insect that is highly destructive to Vines, Melons, and various plants: it does not, so far as we know, attack any other insects. The parasites to which you refer are quite different from the red spider, and will not attack your plants.

**Names of Plants (*A. D.*).**—*Pelargonium quercifolium*. (*J. T. S.*).—The specimens shared the usual fate of those that are simply enclosed in letters. From the smashed mass of vegetable matter we think we can distinguish No. 2 as *Sedum speciosum*; 3, *Lamium maculatum*; 4, *Anemone nemorosa flore pleno*, and 7 as *Stellaria Holostea*. The others are totally beyond identification. (*H. S.*).—Where sprays are simply enclosed in letters, and especially when they remain in the post office throughout Sunday, they almost invariably arrive in such a withered condition that the species cannot be identified. If we receive a specimen in suitable condition we will name it for you. (*S. R. B.*).—You are right about the *Bougainvillea*; it is a remarkably fine example of *B. glabra*. The small yellow flower is *Corydalis lutea*; the tufted *Veronica*, *V. repens*; the *Spiraea* a golden variegated form of *S. Ulmaria*; and the pale green plant with deeply lobed leaves is the American Puccoon or Bloodroot, *Sanguinaria canadensis*. (*A. P.*).—The specimen with white flowers is *Pyrus Aria*, the other is *Ruscus hypophyllum*. (*J. E.*).—*Cytisus Adami*. It was originated by Dr. Adam of Vitry, and was a bud sport from *Cytisus purpureus* inserted in *C. alpinus* in 1825. (*Longhurst*).—*Cerasus Padus*, the Bird Cherry. (*Constant Reader*).—The single flower is *Rhodanthé Manglesi alba*. The double flower we cannot determine from the specimen sent; if you send us a specimen of the foliage and describe the habit and nature of the plant we shall possibly be able to supply you with the name. (*W. E. B.*).—1, *Todea pellucida*; 2, *Todea superba*; 3, *Pteris tremula*; 4, *Doodia media*; 5, *Maxillaria tenuifolia*; 6, *Oncidium flexuosum*. (*F. C.*).—The specimen was not in good condition for determining its name, but it closely resembles *Asplenium aculeatum* var. *Brauni*. (*Old Subscriber*).—1, *Geum coccineum*; 2, *Centaurea montana*; 3, *Cheiranthus alpinus*. (*G. S.*).—Through being packed in cotton wool the small specimen was so withered as to be quite unrecognisable. (*E. W.*).—1, Too withered; 2, *Maxillaria Harrisonæ*, fine variety; 3, a smaller variety of the above; 4 appears to be a deformed variety of *Lycaste aromatica*. (*J. McD.*).—*Fraxinus Ornus*. (*A. C.*).—*Limnanthes Douglassi*.

**Supernumerary Queen Cells (*Buzz*).**—The queen cells built by the natural impulse of the bees in preparation for swarming will, of course, do for insertion in freshly swarmed hives. We prefer these to others if we find them ready to hand. The queen from this hive has undoubtedly been lost.

**Fertile Workers—Comb Foundation (*Idem*).**—Fertile workers are not produced in queen cells, but appear rarely in queenless stocks. They are workers exalted by an impulse to produce progeny into pseudo-mothers capable of laying drone eggs but incapable of fertilisation, and so incapable of depositing fertilised eggs and so producing workers. Both samples of lozenge-bottom foundation are good, the thin trellis also. This is suitable for sections only. Drone foundation is dangerous in sections where the drone comb in the hive is kept down in quantity. Drone in sections then attracts the queen, and the supers are more or less spoiled; but it is true that drone comb is more quickly built and stored than worker.

**Clearing Bees off Combs for the Extractor (*F. J.*).**—Before removing combs for the extractor do not puff smoke into the hive mouth, as this drives bees towards the end combs which you require to clear, but rather turn back the quilt off the end frame and puff down smoke between it and the hive side. It is a good plan to put a large board with one edge resting upon the alighting place, upon this jerking off the residue of bees, which of course immediately run in. If this trouble be considered excessive the quilt must be wholly removed, and the bees shaken down upon their frames. Some recommend a goose wing for whisking off the few remaining stragglers, but we use and recommend a painter's dusting brush as being decidedly superior. The brush is moved very quickly, and the ends of the hairs only are employed; so that the bees have no time to get between them, but are simply knocked away without injury to themselves. A little practice will soon give dexterity in handling it.

**Empty Queen Cells—Queenless Stock—Expelling Drones (*H. M.*).**—The cells you supposed to contain developing queens were without question empty from the first, and were either the remains of cells which had been the cradles of queens in a previous year and had been subsequently cut down, or were abortive cells which the bees in some inexplicable freak occasionally build—e.g., it is quite common, if foundation be given to stocks raising a new mother, for them to draw out a few incipient royal cells upon its face. The destruction of the drones is peculiar. Had the weather been cold we should have supposed that some of the brood had died of chill, or that the combs

had not been put together in due order, and that some of the drone larvae had been in consequence injured; but you speak of "worrying their drones," which is—for a well-nourished queenless stock, and when honey abounds in the flowers—outside our experience.

**Abolishing an Old Skep (*J. K.*).**—As you have already made an artificial swarm from your skep, we should recommend you to wait until three weeks after the operation before doing anything more. Then the last laid egg will have been converted into a perfect bee, while the young queen—unless queen cells were already formed at the time of driving, about which you give us no information—will certainly not have commenced laying, and probably not have mated. If you then drive your hive bare you will leave only broodless combs, while the honey will be at your disposal. Whether this second swarm should be added to the first is a question, and certainly care will have to be exercised, or you are likely to have considerable loss through fighting. You have not stated whether your intention is to adopt frame hives or to go on with skeps; but in any case if you mean to unite, the lots of bees to become one must be kept standing close to each other, and at the time of union smoked and sprinkled with thin syrup, scented if you like. The value of this scenting is not proved, but it at least can do no harm. We should operate early in the morning or not before four in the afternoon, when we are not likely to endanger the queen by upsetting everything while she is away on a wedding tour. If a frame hive is to be used we should take away the old queen and cage the young one until next day. Unions sometimes, though rarely, result in the destruction of both queens unless this precaution be taken.

#### COVENT GARDEN MARKET.—JUNE 1.

BUSINESS steady; all classes of goods being cleared and prices well maintained.

#### POULTRY AND PIGEON CHRONICLE.

#### THE CROSS-BREEDING OF CATTLE.

(Continued from page 431.)

To illustrate the practical results of cross-breeding it is necessary to take into account the advantage of pairing animals of different breeds for producing stock best adapted for feeding and fattening for the dairy, and also for rearing young stock to sell, or feeding for veal. At the same time we must not omit the importance of breeding by an alliance of two different kinds of cattle for the purpose of exhibition at our cattle shows, as many noblemen, gentlemen, and tenant farmers spend large sums of money upon their cross-bred cattle, and exhibit most valuable stock.

Let us first consider the crossing or mating of cattle intended for dairy purposes, and even this point must be treated as having several objects in view. We will take first the raising of stock for dairy purposes, for the sale of milk or for cheese-making. Most of the cross-bred animals which were formerly sent to our fairs and markets, but especially in the midland and western counties, came from the north, and were usually the produce of a cow of a good milking breed, although small in size, and a short-horned

bull. These animals were of greater size and earlier maturity than the dam, and still having a constitution that was able to withstand the rigours of the Scottish climate; at present, however, the Irish importations prevail. It is customary for dairy farmers for milk or cheese to select from them heifers for their dairy, but the steers go into the eastern counties for feeding and fattening. These heifers are generally good milkers, and when dry or barren feed well for beef, and are much esteemed for the quantity of lean flesh as well as fat which they afford. There is a second point, however, to be considered whilst these cows continue in breeding—that is, the calf, and its value for disposal as a suckler, for feeding as veal, or for rearing as stores. Some farmers take but little care, so long as the cows continue to breed, as to the male animal selected for use, because the calves are sold when a week or ten days old. If, however, a well-bred Short-horn or Hereford bull be employed the calves are more readily sold, and instead of 20s. or 25s., 35s. or 40s. will be realised for each one. When heifer calves are reared from the best milking cows for the future purpose of maintaining the numbers of the animals in the dairy it is easy to see the importance of having a really good bull, and one if possible reared from a good milking stock. We recommend the home farmer and dairy farmer to depend on themselves more than they have done by raising all the stock they require for keeping up the numbers of their herd, and to carefully rear and breed from such animals as suit their soil and climate in preference to purchasing from a distance.

The question of cross-bred stock for butter-making dairies must now be referred to. Although we prefer to keep a certain number of good milking short-horned cows and a few Channel Island cows, say in the proportion of five of the former to two of the latter, the necessity of so doing to the exclusion of cross-bred cattle is not insisted upon. Here again arise two points in the cross-breeding, for it is important that the main point of milk and butter should be kept steadily in view, and it must not be forgotten that the value of cows when dry or barren is important also. In crossing, therefore, we still recommend mating a Guernsey bull with the short-horned cows, because we always like to breed from larger females, as not only is richer milk obtained through the influence of the male in this case, but the cow influences favourably the milking capacity of the offspring. The best cows we have ever possessed were of a Short-horn and Guernsey cross, yielding an abundance of rich milk, and becoming large shapely animals when dry or barren. In crossing Short-horn and Jersey, especially when the male used is of the former breed and the cow of the latter, we have not seen satisfactory results. Even when a pedigree or well-bred bull has been used, the stock has commonly been small and delicate animals and unsatisfactory milkers as compared with the first-named mode of pairing.

In discussing cross-breeding for early maturity and baby beef, and also for exhibition, the fact deserves notice that Mr. Colman, M.P., besides obtaining other prizes for a younger animal, achieved a great triumph in the four-year-old steer class, where his white and blue roan steer—three years and seven months old, bred between a short-horned bull and an Aberdeenshire cow—carried everything before it, winning also the champion plate for the best beast in the Show. On some other occasions, too, we have noticed in former years that cross-bred stock has surpassed the pure pedigree animals in the same manner. This is great encouragement for cross-breeders to persevere by judicious selections to rear animals of the most profitable description for ordinary feeding as well as for exhibition. In the west of England, the home of the white faces, cross-bred cattle are commonly met with at most of the fairs, as many of the small farmers who keep two or three cows only send them to a pure-bred bull of the district. In this way a cross between the native or Welsh breeds and the Hereford make good fleshy cattle, much sought after by the butcher when fat,

being liked better than the pure white-faced Hereford, particularly when they happen to have a mottled or smoky face. The Devon breeders have done less than any others in crossing their cattle, which are admirably adapted for the soil and climate of their district, besides being much sought after for working purposes. Still by a cross with the Hereford or Sussex they would be much improved in weight and size—a matter of great importance in working animals, as it gives them more power in labour. Most of the cross-bred cattle we meet with at present partake more of the character of the Short-horn than anything else, so that to this breed belongs the credit of having done most towards supplying animals valuable for early maturity. No matter of what sort or amalgamation of sorts the cow may be, a cross with a pure short-horned bull seldom fails to make an improvement in size, quality, and fattening properties, if not always in the milking capacity of the produce.

Many persons think that cross-breeding has been carried to too great an extent, and fear that at no distant date our breeds will be so mixed that it will be difficult to distinguish one from the other. There is, however, an important counterpoise in the fact that so many wealthy gentlemen and agriculturists pride themselves upon the pureness of their breeds of cattle, and that it is their pleasure to preserve them; an instance of which is stated that at the Duke of Bedford's at Woburn Abbey—where some years ago a herd of from thirty to forty pure Herefords was kept, also that a large quantity of milk and butter was required—the farm steward found it impossible to improve the herd in milking and fattening or flesh-producing qualities at the same time, and had often to sacrifice a very fine cow because she gave no milk; or others that were good milkers, but unfit to breed an ox fit for exhibition. Finding also that it was almost impossible to unite the truth of form and aptitude to fatten, according to the required standard in connection with a profitable herd of dairy cattle, it was thought desirable to keep two herds—one for breeding purposes (the dams only rearing their own calves), and the other for dairy purposes. Still it was also eventually decided to try an experiment and keep some twenty polled Norfolk cows, which are notoriously good milkers, and mate them with a Hereford bull. The produce proved much larger animals than the pure Herefords of the same age, and made some really good butchers' bullocks.

#### WORK ON THE HOME FARM.

*Horse Labour.*—Horses are still employed in preparing the land for sowing the root crops, because although in the northern and north-midland districts both Mangold and Swede seeds have by this date been drilled before this time for the most part, yet in the southern and south-eastern parts of the kingdom the best time for sowing Swede seed is during the first and second week in June. If, however, the crop is required to remain in the land during the winter months to be fed off on the land in the spring, those may be sown until the 20th of June, or even later; for, being after a catch crop on very light gravel or sandy land, they often take very well in this way if the seed is drilled the same day as the land is ploughed. This is now the best time to set Cabbage plants, as they will now be strong enough for planting out, even though the seed was sown in March. The method of planting is of great importance. If the land should be moist and fine the plants may be set with the usual planting stick. If, however, the weather should be very dry and the land very fine, whether on the stretch or on the flat, they are best set with the spade. If hand labour is short and the plants strong they may be laid along the furrow and ploughed in. In this way plants buried too deeply require to be released, and covered with the hand hoe where too much exposed. The mowing machines will now be at work in the early districts, in cutting the forward grass, such as Hop Clover and Ryegrass; and in a few days the Saintfoin will, together with other Clovers, be quite fit for mowing. Last week we took occasion to say that field hay may be made with advantage upon the same system of tedding, &c., as park or pasture hay; and this is no random idea, but one which we have carried out in practice with great success for many years. It is not now, as it used to be, a question of much hand labour, for the tedding machine, the horse rake, and the elevator in stacking the hay not only do the work efficiently but in less time—a matter of extreme importance.

*Hand Labour.*—Before the busy time of haymaking commences all those pastures or parklands where Buttercups abound should be

mowed over to cut off the flowers and seed heads of these weeds, for they are very pernicious, not only injuring the butter but also they interfere with the proper consumption of the grass, being distasteful to the cattle.

**Live Stock.**—Cattle in the boxes fattening should now receive Clover cut up and taken to them daily; if not Clover let it be Trifolium, Vetches, or Lucerne. Each of these pay well to feed bullocks with, or young stock intended for baby beef. If some Mangold has been retained it may be cut and mixed with the cake, corn, or pulse meal; in the absence of Mangold, however, succulent grass may be passed through the chaff-cutter to mix with the cake meal. In this way there is not only far less waste of the superior food, but it has a better effect upon the animals consuming it. The ewes and lambs for stock may now be changed from the Saintfoin or old leas during the day to the Vetches and other catch crops at night; and if they are to have cake it should be on the arable land in their night quarters, and if possible it should be given in admixture with Mangolds, in the same way as recommended for the cattle, in order to avoid waste. The cake or corn should never be given alone but mixed with some materials, such as hay damped after being cut into chaff, or otherwise sweet straw chaffed and moistened with molasses—anything to which meal will adhere readily, in order to prevent waste. It will soon be time now to wean the lambs, in doing which we prefer that the lambs should remain on the ground they have been accustomed to for some little time, because they will always be better satisfied when the ewes are removed than when they are removed to other pastures apart from the ewes. If the lambs have been properly fed in advance of the ewes previously it will render the weaning much easier. Where the Somerset and Dorset horned sheep are kept they should now have a choice Hampshire down ram with them, and if early lambs are required shearing should not be done too soon. This applies to ewes off-going in the autumn. The regular stock flocks on the chalk and limestone hills may be shorn directly; they may then be expected to produce lambs in the latter part of November and early in December—quite early enough for breeding flocks of either Dorset or Somerset horned stock. This sort of sheep have an important future before them, and it behoves all the breeders to select rams of the choicest and purest Somerset blood, for in case the old Dorset type should be lost the exchange for the best stock of Somersets would be advantageous.

#### VARIETIES.

**PEA FOWLS.**—A correspondent desires to know where he can procure a few Pea-hen's eggs for sitting purposes and the price. Those who have eggs for disposal should advertise them.

— **THE BRITISH GOAT SOCIETY.**—At the second annual meeting of the British Goat Society, on Thursday last, the Duke of Wellington was unanimously elected President for the year, on the motion of Dr. A. L. Grace (Berwick-on-Tweed). The report of the Hon. Secretary, Mr. Holmes Pegler, stated the Society continues to increase in members, the list having now reached a total of 202. The late successful entertainment of a kid dinner is to be repeated in connection with a Show of Goats at the Alexandra Palace.

— **THE HOP CROP.**—There is said to be every prospect of a good Hop season in the Kentish fields. The recent warm weather and the refreshing rains of the past few days have caused the plants to make considerable progress. The bine is reported free from insects, and with a continuance of the present weather growers will become very hopeful.

— **STAFFORDSHIRE AGRICULTURAL SOCIETY.**—The annual Exhibition of this Society will be held on September 14th and 15th at Staffrd. The Show will include stock, implements, and poultry. Entries for stock and implements close August 13th, and poultry August 27th.

— **POULTRY AT THE BIRMINGHAM DAIRY SHOW.**—Poultry are well represented, as will be seen by the following figures, which express the number of pens of each kind of fowl:—Brahmas 114, Dorkings 70, Cochins 151, French and Game 107; Ducks, Geese, and Turkeys, 58. These are exclusive of the classes for barn-door fowls, dressed poultry, eggs, &c., of which there are over twenty classes, some being confined to Warwickshire tenant farmers or cottagers. The proposed trial of incubators has been abandoned, as it was thought better to show the machines to the public during the week of the Exhibition, and it was found that nothing short of a twenty-one or twenty-eight days' trial would be considered satisfactory by the bulk of the exhibitors. Poultry feeding by machinery will be carried on daily at stated hours, and short practical addresses will be delivered by Canon Bagot on "Continental Dairying;" Mr. Jas. Long on "Poultry-keeping for Farmers;" and also by Professor Sheldon.

— **THE WINGS OF BIRDS.**—Look at a quill feather, and you will see that on each side of the central shaft or quill there is a broad thin portion, which is called the vane. The vane on one side of the shaft is quite broad and flexible, while that on the other side is narrow and stiff; and by looking at a wing with the feathers in their places, you will find that they are placed so that they overlap a little like the slats on a window blind. Each broad vane runs under the narrow vane of the feather beside it; so that, when the wing is moved downward, each feather is pressed up against the stiff narrow vane of the one beside it, like a blind with the slats closed. After the down-stroke is finished and the up-stroke begins, the pressure is taken off from the lower surface of the wing and begins to get on the upper surface, and then to press the feathers downward instead of upward. The broad vanes now have nothing to support them, and they bend down and allow the air to pass through the wing, which is now like a blind with the slats open. By these two contrivances—the shape of the wing and the shape and arrangement of the feathers—the wing resists the air on the down-stroke, and raises the bird a little at each flap, but at each up-stroke allows the air to slide off at the sides and to pass through between the feathers, so nothing is lost. —(St. Nicholas.)

— **THE FLIGHT OF HOMING PIGEONS.**—Too great attention, said Mr. Sparrow in a paper read before the Balloon Society, cannot be given during the rearing of the young. Arrangements should be made in the loft so that when the young can fly around strongly they can be let out by themselves for their morning fly. If let out with the old birds the latter will, after a few circles, pitch, bringing down with them the young, the old birds returning to their lofts in order to attend to their parental duties. But if the young are let out by themselves early in the morning, with a little attention they will at once dart off, and on a clear bright morning get up to a great height, and frequently keep on the wing for two or three hours at a stretch, and clear away out of sight for an hour and upwards at a time. By this sort of exercise they get a good knowledge of the neighbourhood around their home, and it aids them in getting into condition—an essential requisite if birds are to be called upon to perform long journeys. All amateurs do not follow the same system of training; but a little extra care and trouble is never thrown away, but well invested. The system preferred is to take them about a mile from home, selecting a spot as free from buildings as possible, or the young bird, in its initial performance, might "pitch" on some housetop, and this is a bad habit to acquire. In the first "toss," to give them more confidence, two or three might be started together; but afterwards they should be started singly, letting each bird get clear away before another is started. It is surprising how soon they understand what is required of them. Plenty of this sort of exercise for a few miles in different directions around home, will be of good service to the birds. When the route has been decided upon, the birds should be kept in as nearly a direct line as is convenient. In England, 100 to 120 miles for young birds is very fair work, this being equal to 200 on the Continent where the country is flat, and the atmosphere, as a rule, clear. In order to bring out fully the working capabilities of the birds it is necessary that they should be trained during the first season, and it is best to keep them at work in the same direction. Some excellent work is recorded of English birds trained by English societies. The average rate at which Pigeons travel is forty miles per hour, and they generally prefer flying at a height of some 100 to 200 yards.

#### GROWING CHICKENS.

THERE are times of the year when the energies of poultry fanciers are wont to flag. The buying and mating of our breeding pens in the autumn is interesting; we watch eagerly for our first eggs and save them with care; we busy ourselves in the early spring over our sitting hens or incubators, and bestow much attention on our early broods; but when our chickens have become legion, when the weather becomes hot and tiring, above

all when a time of year arrives generally devoted to travelling and "change of air," we are apt to forget our poultry, believe that they will get on somehow, and put aside our hobby, to resume it again when the show season comes round and cups and prizes are again to be won.

There are few things obtainable without toil and trouble, and certainly success in poultry keeping is no exception to the rule. Where chickens are reared solely for the table, and there is no desire to produce fine specimens as stock birds for another year, or winners in the show pen, it is true that, provided they have a good range, a very small amount of attention will suffice for half-grown fowls. The days are now long and insect food is abundant, so that they pick up much for themselves, and may without harm go many hours between their regular meals. But now-a-days most of us wish to produce fine and handsome if not exhibition birds. If we are to succeed in doing so we must have no seasons of neglect. The growth of our young stock must be watched and judiciously helped. If we go from home others must be taught to give some attention and intelligence to the matter.

We have often written against the forcing of young poultry by condiments and stimulants, and need not here repeat our warnings. Chickens which grow slowly and steadily always turn out the largest and best in the end; but we must be sure that they do grow steadily either in development of size or feather, if they do not something is wrong and must be remedied. We say "or feather," because a bird which is producing feathers at once all over its body cannot possibly at the same time increase much in size. Some kinds, as Game and Dorkings, show an astonishing growth of feathers in their earliest days; others, as Malays, Brahmas, and Cochins, are never properly feathered till they are half-grown. The special peculiarities of breeds must of course be taken into consideration, but when it appears that the young stock is not growing, or, worse, if it seems to go back, some steps must be taken at once to give the chickens a fresh start.

Let us look at a few of the causes which check growth, and the remedies for them. The following are the chief of them—1, Indiscriminate mixing of chickens of both sexes and with old birds; 2, Overcrowding on their ground, or even if there be not too many birds for the area, keeping them constantly about the same place; 3, Insufficient housing and bad ventilation of houses; 4, Bad feeding, or too much sameness of food.

1. Where there is but one poultry yard for both breeding birds and chickens it is almost impossible to rear the larger kinds successfully. The old birds peck the chickens and rob them of their food; even if we manage to give them aside enough to eat they are not happy, and experience has shown us that chickens will not thrive unless they are happy and free. It is a common thing to see half-grown broods penned up in miserable wired runs or cages, while the adults are occupying the large yard. This is a mistake; chickens cannot thrive or grow in such a place, while at this time of year with care old birds may be kept healthy in confinement. We do not, however, advise anybody to attempt to rear more than a few chickens for the table, all to be killed off by the time they are four months old, unless there are two distinct runs with separate houses for them. Indiscriminate mixing of the sexes, too, is after they are three months old an evil. Their separation, however, requires judgment. We have often known cockerels pine if taken from a free range and placed by themselves even in a large enclosed run. If separated at eight or ten weeks old, and at first specially well fed, they generally soon become reconciled to the change and continue to grow. We would, however, rather have a really growing and fine brood ranging at large mixed than divide them to be put in small runs. Nothing is so bad as letting forward cockerels run about among the adult hens.

2. Few fanciers realise the importance of from time to time changing chickens to fresh ground, and of thinning out all useless birds as soon as possible. We have always found our own stock most successful in the years when we have most ruthlessly killed all indifferent specimens; indeed, absurd though it may sound, we are often really pleased to find good reasons for discarding some of our chickens when numerous, as we know well that the remainder will benefit by their room. A change, too, of ground will often give a fresh stimulus to growth. Common sense is very necessary for such judicious changes as for all other things. Where there is variety of ground much good may be done by selecting it according to weather. In a dry season we take our most promising chickens to rich damp pastures and orchards, in a wet one to dry and sunny banks with dusting places protected by rocks. Last year we saw a most striking proof of the benefit of a change and removal to a less crowded yard. Most of our Dorking pullets ranged about a valley; it is true that they had many houses at considerable distances, but they congregated

together too much through the dry month of August, and a flock of fifty Ducks often made their way from a piece of water at feeding times and doubtless got the lion's share. A northern fancier applied to us for a pullet, and we candidly told him that we could not part with our two best, but would let him have about the third finest. He was content. Our best pullets of this breed did not continue to grow as they ought, and by the time of the great shows were disappointing after splendid early promise. At a certain show about four months later we made the acquaintance of the purchaser of this pullet and complimented him upon his splendid first-prize bird. To our great astonishment we learnt that it was none other than our own pullet, which seemed to us to have far outgrown her superior sisters; indeed she looked two months older, and must have weighed 2 lbs. more. Such is a practical instance of the advantage of a change to a new air and less populated yard.

3. Nothing is more detrimental to the development of chickens than close and crowded houses. Hot and unwholesome air sows the seeds of maladies innumerable. Only those who have opened the doors of a crowded and ill-ventilated poultry house after a hot night can fully realise how unwholesome foul air really is. On the other hand, the beginnings of cold, roup, and consumption are often contracted from a draught or drip through a time-worn roof. In all these cases a knowledge of the evil suggests the remedy.

4. Bad feeding and too much sameness of food is the last and a very fertile source of young birds' decline. It is commonly thought that anything in the way of grain or meal will do for fowls: this is a great mistake. Corn merchants produce mildewed wheat and heated barleymeal, observing "Here is something that will just meet your requirements, as you are a poultry fancier." It is true that much small and occasionally slightly damaged grain, unfit for grinding, will do well for chickens, but to give them mildewed and heated stuff is the very worst economy. There is little nourishment in it, fermentation takes place, the digestions of the poor creatures are utterly deranged, and what living creature can thrive, much less grow rapidly, when the digestion, the source of all its nourishment, fails? Buy sound corn and sound meal. Probably you have to pay a good price for it, but be assured that you get your money's worth in the rapid growth of your chickens, in the strength of their bones and delicacy of their flesh. Not only must food be good, it must be varied. Chickens like human beings get sick of the same diet, however excellent, administered regularly three or four times a day. In the way of grain, wheat which we recommend as a general food may at times be changed to barley, a little maize, or, better still if it can be got, to *dari*. The meal can be mixed in various ways. Sometimes bran, a good former of bone, can be added to the oatmeal porridge instead of barleymeal; sometimes quite a small amount of Spratt's food boiled or scalded can be mixed in sharps and the oatmeal discontinued. Boiled rice in hot weather makes a good variety, and kitchen scraps seem always to induce an appetite where all other things fail. Lastly, if chickens become dainty without any apparent cause a judicious day's starving will often bring back their appetite and cure satiety.

There is one more cause of growth being checked which we have almost omitted, because we have too often insisted upon perfect cleanliness in houses and runs for it to seem necessary; we mean parasitical vermin. Infested by such a plague chickens cannot possibly grow. We have often given remedies for it, and only now mention the subject because a young fancier might possibly see his young stock droop mysteriously and have no idea of this occult but very disagreeable cause. However, we believe that chickens are almost always weak or ill from some other cause before they are tormented much by insects. Strong birds rid themselves by natural means of such enemies, while weakly ones succumb to them.

An intelligent person will soon observe when chickens flag or fail, and will almost intuitively see the cause and remedy. We offer these few suggestions to those who have little experience in gallinaceous birds, or whose time is too much occupied for real study of their habits.—C.

## PRACTICAL SCIENTIFIC BREEDING.

### GENERAL PRINCIPLES.

(Continued from page 411.)

WANT of space forbids us entering into any detailed account of the special considerations as to breeding applicable to each variety; and as it is only in this way that much could be said as to the breeding of Pigeons beyond what we have already said as to poultry, we must content ourselves with merely adding a few general hints as to management.

In the first place, the sexes must be separated until about the middle of February, as well to prevent too early breeding, which would be injurious to the hens, as to avoid any mating between birds which it is not desired should mate. When the breeding season arrives each pair of birds intended to mate with each other may either be put in a loft by themselves until they have paired, or they may be put into a pen constructed in two compartments with a moveable wire partition between the compartments, so that the birds can see each other through the partition, and then after a few days the partition should be withdrawn. The matching-up can generally be managed in this way, but should the hen be inclined to lord it over the cock it may be necessary to keep her confined in the dark for a few days and then return her to the pen, to which the cock will in the meantime have become accustomed, and of which he will regard himself as master. In three or four days after they have mated the birds may be returned to the breeding loft, but not more than one mated pair should be set free at the same time, as this may lead to quarrelling for nests and other undesirable disturbances. The breeding loft should be reserved exclusively for mated birds, as the presence of odd birds frequently causes jealousies which are not always groundless. Pigeons are generally faithful once they have regularly mated, but exceptions are by no means rare; and nothing is more provoking to the fancier than to find that a match, upon the bringing about of which much trouble has been expended, has been broken through the intervention of some unmated bird incautiously left in the loft.

If an accidental alliance has been formed which it is desired to break, the hen should, after she has laid her eggs, be removed, kept about a fortnight in seclusion, and then introduced in the usual way to the new mate intended for her.

The first egg which the hen lays should be removed from the nest and an imitation or hard-boiled egg substituted for it until the hen has laid her second egg. This is done to avoid the earlier hatching of the first laid egg and the consequent undue advantage as to feeding which the bird hatched from it generally obtains.

To prevent an excessive strain upon the constitutions of the birds the breeding season should not be unduly prolonged, and all birds which are not actually engaged in hatching or rearing operations should be separated about the middle of August, those so engaged being separated a little later as opportunity offers.

The more delicate breeds, and some which from the character and shape of their beaks are ill adapted for feeding their young ones, require to be supplemented by a supply of nurses to take charge of the youngsters. These are generally chosen from amongst the hardier breeds, best suited by their nature and disposition for the task imposed upon them, or are common Pigeons specially bred for the purpose. The change of the young Pigeons to their foster-parents is sometimes effected while they are still in the shell, sometimes when they are about eight days old and have consumed all their own parents' "soft food," as the natural secretion upon which the young Pigeons are at first fed is called. If the change be made while the birds are still in the shell it must be only between birds whose eggs were laid within a day or two of each other that an exchange is effected, as otherwise the supply of soft food will not be ready for the youngsters when they make their appearance. Again, if the transfer to the foster-parents be made when the birds are a few days old, care must be taken that they are transferred to birds whose own offspring are, if anything, rather younger than their foster-children, and who will thus be able to supply them with soft food adapted to their digestive organs.

An essential distinction between the breeding of poultry and Pigeons is this—that whereas poultry breeders but rarely think of crossing-in a bird of another colour to improve the colour of a strain, Pigeon breeders constantly resort to this expedient, and indeed, as to some varieties, habitually breed from birds of different colours mated together. This renders it necessary that the young Pigeon fancier should, in addition to learning the points of the breed he takes up, also be careful to ascertain the most desirable crosses for the production of sound colour, and of the other points of colour which are so important in the show pen.

Oriental fanciers have even gone further in their desire for variety and their search for improvement, and have produced birds which will not breed true to colour if mated with other similar birds, but which require for their mates birds of a different shade. These varieties owe their origin to the mingling of three or more colours in one bird; and as the process by which they were produced undoubtedly required the employment of successive various crosses, so a like method of breeding is necessary for their perpetuation. For the successful breeding of these varieties considerable skill is necessary, and young fanciers, how-

ever much they may admire the variegated plumage of the Sati-nettes and Blondinettes, will do well to begin with something more simple, and in which success is not so problematical.

(To be continued.)

### DOVERIDGE POULTRY SHOW.

I FEEL gratified by the tone of the remarks made by "C." in your last paper about the arrangements of this Show. I cannot quite understand about the "guarantee for good management of a prospective show"—viz., "that it should be regulated by practical fanciers." Is it necessary to constitute a practical fancier that he should keep several kinds of fancy fowls? My fowl house door is covered with prize and commendation cards for Houdans, the only breed I have kept, and those I have regularly exhibited since 1871. My coadjutor the Secretary has not been long in the fancy, but he has, perhaps, more different breeds than I possess specimens of the kind I keep, and his fowl houses almost amount to a small village. I know he has been a successful exhibitor, but I do not know to what extent. If the public will send us plenty of entries we will endeavour to manage the Show practically and properly. Our schedule is now ready, and I hope it will be considered a fair attempt for beginners.—E. J. BLAIR.

[A reperusal of "C.'s" comments will convince Mr. Blair that no slight was intended to be cast upon any of the persons named in connection with the Show. "C." merely stated that as a rule it is desirable to have a committee of practical fanciers, and in this respect we must say that we entirely agree with him.—ED.]

### OUR LETTER BOX.

**Chickens not Thriving** (*G. P.*).—The long-continued dry weather has probably been the cause of your chickens not doing so well lately. Chickens always do best when there is a fair supply of moisture in the atmosphere. Have you tried the effect of a plentiful supply of green food and a little meat daily? We have not so far had many complaints as to success in rearing this season.

**Chickens Ailing** (*Curate*).—It is impossible to tell from the imperfect account you have given what (if anything) is the matter with your chickens. You say they have a dark rim round the eye, but you do not state of what breed they are or give any other particulars. It may be that the rim you speak of is natural marking; in any case it could not be caused by anything done to the eggs.

**The British Goat Society** (*A. L. N.*).—The address of the Secretary is H. S. Pegler, Esq., 346, Strand, London, W.C., from whom you can, we think, obtain the information you require.

**Muzzling Dogs** (*Protection*).—Professor Ferguson says:—"The wire basket or cage muzzle, when made sufficiently large to admit of the jaws being opened apart for drinking and tongue-panting, is a humane and efficacious invention. It effectually prevents the animal from doing mischief with his teeth, while it allows sufficient freedom to the mouth and tongue for his comfort. The mere screen muzzle of wire projecting forwards from the upper part of the nose, leaving the under jaw and mouth uncovered, is often found ineffectual as a preventive of biting. All persons muzzling dogs, particularly in warm weather, with the ordinary leather muzzle that prevents the opening of the mouth, should be punished for cruelty to animals."

### SHOWS AND THEIR USES.

JUST as the great industrial exhibitions, international or local, general or special, contribute to an expansion of trade, inciting also to quicker production and skilled workmanship, so must exhibitions of products of the soil have the same results. They give an impetus to those engaged in the twin occupations, which together form the greatest and most important of all British industries—agriculture and horticulture; impelling those onward who have hitherto lagged behind, and nerving those who have won their spurs not only to maintain their positions but to increase their prowess. This is what is accomplished by public exhibitions; indeed such results are their natural outcome, for there is implanted in the human mind a desire to excel. Were this not so, and did not the results indicated follow as if in obedience to a law of Nature, exhibitions would be anomalies, and would long ago have died of inanition. But so far from the exhibitions that represent both agriculture and horticulture diminishing in size, decreasing in numbers, failing in variety, or lacking in interest, the exact reverse appears to be the case, for they are larger, more numerous, more varied, and appear to attract greater attention than ever. Indeed, the spirit of emulation is so predominant that there is—and it would be a great wonder if it were not so—about as much rivalry among promoters of shows as prevails among exhibitors.

A very practical question is now often asked—namely, Have the results that have generally accrued, say in agriculture and horticulture, been proportionate to the efforts that have been made to produce them? Is the cultivation of the present generation so far superior to the system of the past that farming is more profitable, and gardening more productive and enjoyable, than before? An affirmative reply cannot be given to the first, and, it will be conceded, the most important question; but this is certainly not the result of exhibitions, but in spite of them. Agriculture is not prosperous now, but the cause is wholly beyond the influence of any “shows;” and as no one can define it in a sentence, it will be convenient to attribute it to a “fortuitous concurrence of atoms,” and there leave it for polemical controversy. But another question of some moment arises—Were it not for the knowledge that has been gained by public exhibitions, would not the depression that has prevailed during the past few years be greater than it is now? According to such logic as is derivable from negative evidence, the presumption is that the depression would certainly not have been less, but probably would have been

much greater; yet there is no denying the fact that the cultivators have had to bear, and are bearing, the brunt of the “bad times,” and their allies the machinists and others have so far had the best of the “improved systems” that have been instituted. Without machinery—thrashing machines, mowing machines, cultivators, &c.—the agricultural state of this country must inevitably be in a worse condition than it is now, because it would be deprived of the material that is necessary in the battle of competition. Shows, then, have done great good in having brought valuable inventions before the public, and especially to those who have prudently availed themselves of them, much emphasis being laid on the word “prudently.”

But to the second primary question as applied to gardens. Are gardens more productive and enjoyable than before horticultural shows were so general? It is a question if they are more productive, as judged from an utilitarian standard. The old kitchen gardeners of the past generation were as competent in their calling as the young men of the present time; and the hardy fruit culture of half a century ago was as good as it is now, and in some respects probably a good deal better. The grand and fruitful old espaliers and magnificent wall trees trained by the grandfathers of the present adult generation of gardeners have mostly disappeared, and have in few cases been substituted by trees equal in every way to the originals. Fancy forms have been inaugurated, and varieties have been increased, perhaps too much increased, yet some are improved; but the fruit supply is not better than it was before shows were so numerous. Exhibitions, then, have done but little good in the hardy fruit department of the garden. Neither have they in the outdoor vegetable department. That this is so we have pretty conclusive evidence from the superior products of the best market gardeners—men who have no time for visiting shows, and yet whose produce, there is reason to believe, has by some means had the honour of being arranged in the winning stands of vegetables at some of our greatest exhibitions.

Turn we now to another phase of the question, and withal a most important one. Without, like certain individuals of artistic proclivities, making too much of the fashionable word æsthetics, it must be stated that the term has some application to the department now under consideration, which undoubtedly represents both what is ornamental and useful—the term useful being founded on and applicable to anything that is necessary. This branch of gardening is the outside floral, and under glass section—the latter, of course, including fruit as well as flowers. There are some who have the habit, a pedantic one probably, of asserting that the present state of gardens, flower gardens especially, are strikingly destitute of taste. Be this as it may, it is not the result of flower shows. It would, however, be an unfortunate monotonous world if all gardens were arranged according to the taste of one or two individuals, as it might happen they may have errotchets, and crotchety people are proverbially not the most reliable of guides.

Now, in the department under notice, the forcing and growing of fruit under glass, and the production of plants and flowers in the homes of the affluent—and it would be well if they were represented as far as possible in the homes of all—there has been great improvement of late years. The supply is better, more choice and continuous, than formerly. To this improvement flower shows have materially contributed. They

have in the first place created a desire on the part of innumerable exhibitors to have what they have seen produced so well; and have proved magnificent object lessons to the searchers for knowledge, and have afforded examples of skill that they might emulate. In other respects the shows have been of great use, for they have encouraged mechanical and scientific enterprise in the designing and erection of structures and heating them effectually and economically, also in giving a stimulus to inventors, and encouragement to improvers of labour-saving implements and appliances. All this is beneficial, alike to the fabricators, as it ought to be, and to those who enjoy the fruits of their skill and labour.

The widely extending and ever-growing love of plants and flowers that is a characteristic of the present era, and which will without doubt continue to expand, is of great benefit nationally, professionally, and individually. It appears to be an element in our being that man must have something to foster, woman something to love. What more worthy of the intellect of the one and the heart of the other than flowers? Stars of earth they are, as the great bard sang, and emblems of heaven. Societies do well to encourage their culture, and their shows create a taste that is health-giving, mind-expanding, and in all respects salutary. The "appetite growing with what it feeds upon," is ever making fresh demands; and forthwith men of enterprise formed trade establishments that became great, even of world-wide fame, and other men are found who will risk health and even life in the pursuit of the vocation that has been created.

The tendency of the times appears to be towards utilitarianism even in plants. It is not the fashion now to spend half a dozen years in growing a specimen Heath, nor for a stout man to sit for two days tying the plant into "form." The stiff ideal form of the old plantsmen is being supplemented by a style partaking in some degree of the delightful freedom of Nature. Grand specimen plants are always admired, but those are most in repute that are of quick growth and free, not slow in movement, stiff and formal. In these electricity days quick returns are in fashion; these the smaller plants afford—useful plants that are adapted to other purposes than exhibitions—namely, the adornment of homes. Beyond question the custom, for custom it now is, of giving prizes for the grouping of small plants artistically at exhibitions, first advocated in this Journal, has been successful in various ways. It has increased the number and variety of plants exhibited both at metropolitan and provincial shows; has enabled new and rare, even if small, plants to be brought forward with greater advantage than formerly; has developed taste in arrangement; and has extended the trade for plants to a greater extent than elephantine specimens alone could possibly have done. Yet undoubtedly grand examples of culture should be encouraged, especially as Heaths and other hardwooded plants are so valuable for decorative purposes when in a comparatively small state.

It would seem to follow from this that while shows have been of undoubted benefit, those engaged in commercial plant culture have reaped the greatest advantage from them. This probably is so. Purchasers of plants have had their home pleasures enhanced after admiring the plants at shows and procuring them; gardeners have by visiting the exhibitions become more skilled cultivators; and some of them who have the privilege of devoting the resources at their command to showing as a system—a profession—have derived, as they have deserved to do, pecuniary profit; but the vast majority have had to be content with honour. The costs of travelling, &c., even in these big prize days, have too often left no margin; but this little, somewhat strange to say, some employers have appropriated. They have a right to do this; but it is happily rarely the custom to enforce that right, for those who have had experience in showing know that the men who win have spent hundreds of hours working when they might justly and lawfully have been resting. Large prizes to enable gardeners to cover the expenses of exhibiting appear to be indispensable, for they have no indirect gain; but such prizes are less needed by those to whom shows and press notices bring much business; and the majority of nurserymen have the reputation of being true horticulturists, and do not regard shows and societies as organisations for directly compensating them for their immediate outlay.

Draining societies, whose sole and only object is the promotion of horticulture, is a bad policy, and almost tantamount to killing the goose that lays the golden eggs. They should be supported, not exhausted, for their promoters labour without reward, except that of fostering the industry that they believe is fraught with benefit to all. Their managers, London and provincial, often receive as much of obloquy as honour. They deserve a better fate, and merit support—steady, regular, and continuous; for shows more frequently result in loss than gain, and whatever profit may occasionally result is devoted to the more effectual

furtherance of the great object of their being—the advancement of horticulture.

Still shows and showing must never be regarded as the be-all and end-all of gardening, for it is a fact that the names of many of the best cultivators of plants, flowers, and fruit are never seen in exhibition lists at all; and it is a little curious to notice the number of those who show and lose who "have left their best things at home!" Even to such people shows are useful, as they teach that this policy seldom brings them either sympathy or profit.

#### METROSIDEROS FLORIBUNDA.

THIS fine old greenhouse plant, which is known as the Bottle-brush Tree, is seldom seen now. I am surprised it is not more generally grown, being so easy of culture and free-flowering when well established. I find it very useful for cutting. The shape and colour of the flower spike is very telling when mixed with other flowers. The plant produces its flowers all through the spring months, but just now it is a perfect picture, having forty spikes of bloom out. It is growing in a 10-inch pot, is 5 feet high, and 3 feet through. It has not been shifted for three years. I find it flowers more freely when rootbound. I enclose a spray for your opinion thereon.—STIFFORD.

[It is a fine example of a fine old plant.—ED.]

#### APPLE TREE ON A PLUM STOCK(?).

INSTANCES of fruit trees succeeding on stocks of different yet allied genera are exceptional, confined, so far as I know, to the Pear, Apricot, and Peach. The Pear succeeds on the Quince (*Cydonia vulgaris*), Hawthorn (*Crataegus oxyacantha*) Mountain Ash (*Pyrus aucuparia*), and Medlar (*Mespilus germanica*). Apricots are invariably on Plum stocks, usually Mussle. Peaches and Nectarines thrive remarkably well on Plum stocks, and in certain localities are successful on the Almond (*Amygdalus communis*). The Medlar succeeds on the Quince, Hawthorn, and Pear. In all cases there is affinity in sap. Those with gummy sap, as the Cherry, Plum, Peach, Nectarine, and Apricot, do not succeed on those which have not descending gummy saps, as the Apple, Pear, Quince, and Medlar. The stone fruits require stocks of a similar nature; and so with the others—those with pips do not thrive on stone-fruit stocks. The Apple and Pear, though closely allied, do not afford stocks for each other, although Mr. Knight obtained a heavy crop of Apples from a graft inserted in a tall Pear tree only twenty months previously. The graft, however, perished the winter following.

Having repeatedly heard of an Apple tree on a Plum growing at Grinkle Mill, Easington, North Riding of Yorkshire; and upon inquiries of the present occupier and grafter, Mr. T. Wren, I went to see the tree, which I understand was one of a group of three Wyedale Plums. The stems of the trio are only a few inches apart, but are separate to the ground, and have evidently sprung from one root stem, probably that of an old tree of the same kind. The stems of the Plums are clearly those to the base, as they are emitting suckers freely; but whilst that upon which the Apple has been worked indicates its Plum origin at the base it does not produce suckers, and the bole gradually loses its Plum bark upward until it entirely disappears in that of the Apple some distance below the junction of stock and scion. The point of union is still clearly indicated by the bark, and the only visible effect has been to gradually increase the stock, it being somewhat stouter than those of the Plums, and to cause it to assume the character of the bark and wood of the scion.

The only question is, Is it really a Plum stock? The appearances all go to verify the statement of the operator—viz., that it was a Plum and bore Plums like its two companions until it was grafted with the Apple, which was done out of that youthful inclination for trying experiments often leading to unexpected results. It was grafted late in the season, had leaves and Plums on when headed, and has borne for many years crops of Apples, and promises an abundant crop this season. When I saw it the pink blossoms were showing amid the snowy white of the Plums. It is worked at about 7 feet from the ground, and gives no indications of shoots on the stem below the junction. The tree is in apparent health, but for its age is comparatively small, yet somewhat larger than its Plum companions. The variety of the Apple is Holland Pippin, one of the best and most certain in elevated localities; the Plum (Wyedale) being one of the best late, and certain cropping varieties for culinary purposes.—G. ABBEY.

SYCAMORE GROWING IN A LABURNUM.—On being shown over the grounds attached to Merlin, near this town, a few days since,

by Benjamin Fayle, Esq., I noticed the curious circumstance of a Sycamore growing out of the centre of a Laburnum. There was no soil nor vegetable matter nor any other feeding material visible to support it, and there seemed no tangible explanation, except that the seed ("key") fell there, grew, and that the roots are now indebted to the sap circulation of the stock for existence. It may be worth the notice of Dr. Hogg and the Rev. G. Henslow. Cases of parasitic growth on tree-decay are common, but this is different.—W. J. M., *Clonmel*.

[We suspect this is not a true parasitic growth.]

## ROYAL HORTICULTURAL SOCIETY.

GREAT SUMMER SHOW, JUNE 3RD TO 7TH.

PRESUMABLY with the view of embracing the Whitsuntide holidays, and affording the great populace of London and its environs an opportunity to visit the Show, the opening day was changed from Tuesday to Friday, the Exhibition continuing over Sunday till Tuesday night. Whether the change has proved as advantageous as was anticipated we are not able to say; but it may be said that five days appeared to be considered too long by some of the trade exhibitors, for Messrs. Veitch & Son did not show at all, Mr. W. Bull only staged two collections of twelve plants each, and Mr. B. S. Williams Orchids, Ferns, and a miscellaneous group, not including his choicest examples, which were either at Holloway or Manchester. Under these circumstances other nurserymen and floral decorators were the more prominent, and they have shown that they possess great and varied collections of popular and valuable plants—even sufficiently so, with the amateurs' collections in competition, to fill the huge marquee and a great portion of a tent 200 yards long. The General Horticultural Company sent a collection of great magnitude and merit; Messrs. Laing and Cutbush large and varied groups, the latter including splendidly grown examples of *Erica Cavendishiana*; and the former, with Mr. Coppin, also staging gorgeous groups of Tuberous Begonias; Messrs. Jackson of Kingston and Peed of Norwood sent magnificent stove and greenhouse plants; Mr. George Paul contributed gigantic Roses, and Messrs. Osborn, Barr, and Ware sent fine herbaceous and alpine groups, while Messrs. Dick Radcliffe & Co. and Mr. Aldous contributed materially to the effect of the Exhibition. Amongst cut flowers Mr. Turner exhibited very fine stands of Roses, Messrs. Veitch of Exeter a grand box of the old *Devoniensis*, and Messrs. Kelway and Ware Pyrethrums, the single varieties almost causing a sensation, and kept the attendants busy booking orders. Among the amateurs' collections Mrs. Torr's Azaleas were of remarkable merit, Mr. Warren's *Gleichenias* were superb, and Mr. Whitbourn's Orchids finer than ever. Thus were the tents filled, and they were even brighter than usual, flowering plants predominating where before fine-foliaged plants have often been in overpowering numbers; in fact, on this occasion more of large Palms and Ferns were almost needed as a foil to the dense masses of colour. Fruit—except some of the prize collections of Grapes, Lord Brownlow's Bananas, Lord Fortescue's Pines, Lord Carrington's Cherries, the Marquis of Salisbury's Strawberries, and the Melons and Cucumbers in competition for Messrs. Sutton & Son's prizes—was not remarkable. Vegetables were good, the winning collections fine, and the display of implements, &c., outside was the most extensive that has ever been seen in the gardens. The weather on the first two days was brilliant—hot, and the company, on Friday especially, was brilliant too. On Monday heavy showers fell at intervals, and Tuesday was dull and wet generally. This sudden change must have materially limited the attendance; but the rain has been of far more benefit than all the shows to a parched land.

### STOVE AND GREENHOUSE PLANTS.

The liberal encouragement given to growers and exhibitors of these plants was cordially and freely responded to by gardeners and nurserymen, and as a result visitors were gratified by a large and satisfactory display of well-grown specimens, representing all the chief species and varieties usually included in such collections. In the three classes provided a total sum of about £90 was offered in nine prizes, for which there appeared ten competitors, who staged nearly one hundred specimens, mostly characterised by admirable freshness, symmetrical training, and abundance of flowers. The principal class was for twelve plants in flower, and was open to all exhibitors. Messrs. T. Jackson & Son, Kingston, Surrey, had a particularly strong and meritorious collection, easily securing the coveted premier award. The Kingston specimens are well known at the early summer shows, but the most noteworthy may be briefly indicated for the advantage of those who have not had the pleasure of seeing them. That almost indispensable plant in such classes, *Dracophyllum gracile*, was represented by a specimen 4 or 5 feet across, very evenly trained in a globular form, and flowering profusely; *Pimelea mirabilis* was of similar dimensions, and equally excellent in other respects; a large example of *Azalea Grand Crimson* had a great number of fine brilliantly coloured flowers; *Hedera tulipifera*, a symmetrical glope-shaped plant bearing numerous blooms; *H. fuchsoides*, not so large but very neat; *Clerodendron*

*Balfourianum*, *Aphelexis macrantha purpurea*; *Azaleas* Criterion and Model, with three handsome Heaths—*Erica ampullacea*, *E. Cavendishiana*, and *E. Lindleyana*, completed the collection. The excellent even training of these plants was especially noteworthy and merited the admiration they received. The second prize was adjudged to Mr. E. Tudgey, gardener to J. F. G. Williams, Esq., Henwick Grange, Worcester, for plants of considerably more than ordinary merit generally, but perhaps a little deficient in the symmetry which formed such an important feature in the preceding group. *Anthurium Schertzerianum*, 5 or 6 feet in diameter, had about forty spathes very large and brightly coloured, the health of the plant also being remarkable. An *Erica Cavendishiana* of extraordinary size was in excellent condition and bearing very large flowers. *Erica ventricosa* was also represented by a beautiful specimen, and several other good examples of cultural skill were contributed. Messrs. B. Peed & Son, Lower Streatham, were third with rather rough and small plants compared with the others, but *Allamanda grandiflora* was well shown, both foliage and flowers being fine.

For eight plants from nurserymen the last-named exhibitors were placed in the chief position with a satisfactory collection, including several handsome plants, of which the best were *Statice profusa*, 5 or 6 feet in diameter, unusually vigorous, and bearing numerous trusses of the rich blue flowers distinguishing the species. *Erica affine* was another notable plant, compact in habit, the light yellow flowers contrasting strikingly with the dark green foliage. *Allamanda grandiflora*, *Aphelexis macrantha purpurea*, and *Azalea Juliana* formed the other chief features of the group. Messrs. Jackson & Son followed closely with neat specimens, similar to those in the previous class, but smaller and scarcely so well flowered; while Messrs. J. Peed & Son, Ronpell Park, were third, staging among others a well-grown *Franciscea calycina* major with abundance of its large rich purple flowers. In the class corresponding to the last, but appropriated to amateurs, the principal honours were adjudged to Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, who staged some good examples of the most popular exhibition plants, such as *Bougainvillea glabra*, very large, and trained in a globular style; *Erica Cavendishii*, healthy; *E. depressa*, vigorous and informal; *Hedera tulipifera*, even; and *Aphelexis macrantha*, neat, besides others but little inferior to those named. Mr. Tudgey was a good second, his plants though small being very neat; and Mr. Watson, gardener to D. Martineau, Esq., Clapham Park, was third with clean specimens.

### AZALEAS.

Three classes were also devoted to greenhouse Azaleas, which formed an important portion of the display in the large tent, as in two of the classes the competition was fairly close and interesting, the specimens shown in the winning collections being especially remarkable for the profusion of their flowers and the brightness of the colours; indeed, such glowing masses of colour were contributed that in some portions of the tent a few additional fine-foliage plants would have added considerably to the effect by toning the brilliancy of the Azaleas; but though the former were not forthcoming in sufficient numbers very great care was taken in their arrangement, and with admirable results. In the class for eight distinct Azaleas from nurserymen there were four entries, but only two exhibitors appeared—namely, Messrs. T. Jackson & Son and B. Peed & Son, who were respectively awarded the first and third prizes. The premier collection included very neat examples, the varieties best represented being Bernhard Andreas and the well-known exhibition kinds *Souvenir de Prince Albert* and *Duc de Nassau*, all flowering freely. In the other group the plants were mostly small and of irregular form, but in moderately good condition as regards flowers. The corresponding class for amateurs was well filled, four competitors appearing. Mr. J. Child followed up the success he has this year attained at several other exhibitions by securing the chief honours for the large handsome Ewell specimens, which were in excellent form, and were greatly admired. The varieties *Cedo Nulli*, *Barclayana*, *Reine des Belges*, *Model*, and *Sir Charles Napier* were first-rate, not only in general health, but also in the size and numbers of their flowers. Following closely came Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham, who staged his tall pyramidal plants in fair condition, but some were slightly rough and deficient in flowers. *Juliana* and *Giganteaflora* were, however, noteworthy, and produced a telling effect in the group. Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, Regent's Park, was third, but with the exception of *Apollo*, which was uncommonly bright, the plants do not call for special comment. The competition in the open class for fifteen plants in pots not exceeding 12 inches in diameter was keen, five exhibitors entering the lists. The much-desired first position was adjudged to Messrs. T. Jackson & Sons for even, healthy, globular-trained specimens of well-selected varieties, among which the following were notable:—*Comte Baudouin*, with bright rose-coloured spotted flowers; *Antoinette Thelemann*, a rich red-flowered variety; the deep red *Mons. Keteleer*, the pink-striped double *Mlle. Marie Van Houtte*, with Bernhard Andreas, Jean Verschaffelt, and *Souvenir de Prince Albert*. Mr. C. Turner of Slough was second with small but beautiful plants, as usual bearing remarkably fine flowers, richly or delicately coloured according to the character of the variety. Many excellent varieties were represented, such as *Souvenir de M. R. Abel*, *Mons. Thibaut*, *Roi d'Holland*, *Cordon Bleu*, and *Mlle. Marie le Febvre*, the latter a handsome form, with very large pure white

flowers. Mr. Ratty secured the third prize with small but fairly well-flowered specimens.

#### ERICAS.

Although Heath and hardwood plants do not now receive a tithe of the attention accorded them some years ago, there are still growers and exhibitors of these once popular plants, and the three collections staged in the single class devoted to Ericas at Kensington proved that the skill demanded to obtain them in good condition has by no means been lost. Messrs. T. Jackson, long renowned for such plants, were easily first with clean, healthy, even, and well-flowered specimens, among which *E. tricolor* Wilsoni and *speciosa*, *E. Lindleyana*, *E. Spenceriana*, *E. affine*, *E. ventricosa coccinea minor*, and *E. v. tinctoria rubra* were particularly fine. Mr. Tudgey, who was second, also had several handsome examples, *E. ventricosa magnifica*, *E. mirabilis*, and *E. Cavendishiana* being the most striking. Messrs. B. Peed & Son were third with decidedly the least satisfactory plants, but including an *E. ventricosa magnifica* in good condition and very evenly trained.

#### ORCHIDS.

No summer exhibition of any importance is now complete without one or more classes for Orchids, and when these are moderately well filled they generally form one of the most attractive portions of the display. The interest in these beautiful and peculiar plants so far from diminishing seems to be fast increasing, and on Friday last there was scarcely any part of the Exhibition more crowded throughout the day than that where the Orchids were arranged. Three classes were devoted to them, and eight collections were staged of varying degrees of merit, but as regards clean healthy growth they were all satisfactory and some were extremely fine. The chief class as regards the value of the prizes offered was the open one for fifteen distinct species or varieties, in which £20, £15, and £10 were the first, second, and third prizes respectively. Only two exhibitors, however, staged collections, and these, though both of great excellence, varied considerably in merit and occasioned some discussion. Mr. H. James, Castle Nursery, Lower Norwood, was placed first with fine masses forming a beautiful display of flowers, but chiefly what are known as "made-up" specimens—i.e., several smaller plants placed together in one pot. As masses the collection clearly surpassed the other, but in other respects some doubts were expressed as to their relative merits. Mr. James's plants included the following:—*Odontoglossum vexillarium*, with eight spikes of highly coloured flowers; *Cypripedium niveum*, very pretty, with two dozen neat flowers; *Epidendrum vitellinum majus*, with about thirty-six spikes of brilliantly coloured flowers; *Phalenopsis grandiflora* had fairly large flowers; *Oncidium ampliatum* bore five large spreading panicles; *Oncidium concolor* was fairly represented, the plant having thirteen spikes; *Cattleya Mossiae* bore fifteen moderately good flowers; *Aerides Fieldingi* had five spikes; and the other Orchids of less merit were *Lælia purpurata*, *Odontoglossum vexillarium*, *Masdevallia Veitchiana*, *Dendrobium chrysotoxum*, *D. nobile*, and *Cypripedium barbatum giganteum*. The second position was secured by Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, Essex, who had very handsome healthy specimens which some experienced Orchid growers and judges considered equally as meritorious as the first-prize group, the majority of the specimens being single plants very well grown. Among the most noteworthy examples were *Dendrobium Dalhousianum*, with a dozen spikes of its large and peculiar buff-coloured flowers; *D. nobile*, of great size, about 5 feet in diameter and profusely flowered, a well-known specimen; *Cattleya Warneri*, a remarkably handsome variety, with soft purple broad petals and sepals and a rich crimson lip; *Odontoglossum hastilabium*, with three handsome panicles of flowers; *O. Roezlii album*, and *O. vexillarium*, similarly fine; *Calanthe veratrifolia*, bearing five tall handsome spikes of white flowers; *Anguloa uniflora superba*, a fine variety of a distinct species, with creamy coloured sepals and pink-streaked petals, presenting a strange contrast with *Anguloa Clowesi*, also shown. The other most notable plants were *Dendrobium thyrsiflorum*, with five large dense spikes of flowers; and a fine variety of *D. Wardianum*, with two growths each bearing ten flowers.

There were three competitors in the amateurs' class for ten Orchids, Mr. Child being awarded the chief prize for a similar collection to that accorded the same honours at the recent Crystal Palace Show. The most remarkable plant it contained was *Vanda suavis*, with four growths about 5 feet high and bearing half a dozen spikes of flowers. *Odontoglossum citrosmum* had five panicles of flowers, and *Aerides Fieldingi* had a similar number and was in fine condition. Mr. Salter, gardener to J. Southgate, Esq., Selborne, Leigham Court Road, Streatham, followed closely with healthy plants, and Mr. J. Douglas was third with a good collection. In the corresponding class for nurserymen Mr. B. S. Williams, Upper Holloway, secured the principal prize with a good selection of valuable species and varieties, the plants being healthy and flowering well. Some of the most noteworthy specimens were *Dendrobium suavisimum* with a dozen or more fine spikes of bright yellow flowers. *Lælia purpurata* was represented by a good variety, the lip of the flowers being particularly richly coloured. *Epidendrum vitellinum majus* and *Cypripedium barbatum superbum* were of great excellence, and the very distinct *Dendrobium Jamesianum* was also in good condition, among many others of considerable beauty. Mr. James was placed second, and Messrs. Jackson & Son were third, both with fair collections.

#### NEW PLANTS.

Two classes were devoted to new plants, one for twelve sent out in 1880-81, and the other for twelve not in commerce. In each only one exhibitor appeared—Mr. W. Bull of Chelsea, who was accorded the two chief prizes. In the first-named class the following plants were shown:—*Dracæna Lindenii*, very distinct, with recurved leaves 3 or 4 inches broad, with yellow margins and a green central band; *Davallia fijiensis*, a pretty dwarf Fern with bright green finely divided fronds a foot broad and 15 inches long; *Asparagus plumosus*, very elegant, with dark green filiform leaves arranged in a feathery manner, as the name implies; *Anthurium Andreanum*, so well known now that it does not need description: the plant shown had three spathes; *Dieffenbachia Leopoldi* and *D. triumphans*, two new forms of Dumb Cane, the former having dark green leaves and a white midrib, the latter very dark green spotted with white and yellow; and *Aralia spectabilis*, leaves pinnate, 4 feet in length, pinnæ 6 inches long. The following, which have been referred to in this Journal at various times, completed the collection:—*Adiantum aneitense*, *Philodendron Carderi*, *Anthurium insigne*, *Croton formosus*, and *Juncus zebrinus*. In the class for plants not in commerce the following were shown:—*Illicium religiosum variegatum*, a variegated form of the Star Anise, the leaves being margined and flaked with white; *Deyoukia elegans variegata*, an attractive plant with linear, grass-like, narrow drooping leaves, dark green with clearly defined margins of yellow; *Croton insignis*, leaves a foot long and 2 inches broad, green veined with yellow and crimson: very bright and pretty; *Aralia concinna*, leaves pinnate, 1 foot to 1½ foot long, pinnæ 5 inches long and deeply cut; *Sansevieria flabellata*, a peculiar plant with cylindrical dark greyish green leaves like *S. cylindrica*, but channelled on the upper surface and arranged in a fan-like manner; *Dieffenbachia regina*, compact in habit, with elliptical leaves white or light green sparsely mottled with dark green; *Geonoma Bluntii*, a handsome Palm with pinnate leaves 4 feet long, the pinnæ irregular in size and of a peculiar green tint; *Selaginella involvens variegata*, one of the caespitose type, slightly variegated; *Dracæna Pacotti variegata*, leaves tapering, slightly streaked with yellow and green; *Sarracenia flava splendida*, distinguished by large pitchers, the upper part and lid yellow veined with red; *Alsophila tænitis*, fronds bipinnate, dark green; and *Dieffenbachia rex*, a distinct form with large leaves irregularly marked with dark green and yellowish white.

MR. W. BULL'S PRIZES.—The successful exhibitor in the two preceding classes as usual offered prizes, consisting of silver cups valued at fifteen to six guineas, in three classes, each for twelve new plants introduced and sent out by himself since 1878. In the amateurs' class two collections were staged by Mr. T. N. Penfold, gardener to Canon Bridges, Croydon, and Mr. W. Selway, The Gardens, Knight's Hayes Court, Tiverton, who were adjudged the first and second prizes respectively. Mr. Penfold's plants were in fine healthy condition, the following being those shown:—*Carludovica Drudei*, *Croton Chelsoni*, *C. roseo-pictus*, *C. gloriosus*, *Cyphomandra argentea*, *Asparagus plumosus*, *Dieffenbachia splendens*, *D. Leopoldi*, *Davidsonia pruriens*, *Selaginella Kraussiana aurea*, *Calyptronoma Swartzii*, and *Ixora profusa*. Mr. Selway also had vigorous examples of attractive plants similar to those enumerated above, but the following were distinct:—*Croton Williamsii*, *C. princeps*, *C. Challenger*, *Anthurium insigne*, *Encephalartos Frederici-Guilielmi*, and *Sarracenia flava ornata*. The only other exhibitor was F. Yates, Esq., Higher Feniscowles, Blackburn, who entered in the class for amateurs that have not previously won any of these cups. He was awarded the chief prize for small but neat specimens of the following in addition to those already mentioned:—*Lastrea aristata variegata*, *Croton elegantissimus*, *C. formosus*, *Adiantum aneitense*, *Davallia fijiensis*, *Juncus zebrinus*, *Asparagus plumosus*, and *Dieffenbachia Shuttleworthii*.

#### FINE-FOLIAGE PLANTS.

In the one class appropriated to fine-foliage plants four good collections were staged, all by amateurs in accordance with the stipulation of the schedule. The premier group of eight plants was contributed by Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, who as usual had some remarkably handsome plants. An example of *Croton interruptus*, 7 feet high, as much in diameter, and finely coloured, was the chief feature; but several others were also notable, especially *Croton Andreanus*, also of great size and in most vigorous condition, the leaves being very large and beautifully variegated with yellow; *Areca sapida* was about 12 feet high; the distinct and noble *Pritchardia pacifica*, with *Thrinax elegans*, *Dasyllirion acrotrichum*, and *Croton variegatus* being in first-rate form. Following closely was a collection from Mr. T. N. Penfold, including large and healthy specimens of *Croton Hendersonii*, *Cycas nobilis*, and *Spathiphyllum pictum*. Mr. Tudgey was placed third, also with good plants, several Palms, a *Cycas revoluta*, and a *Croton Queen Victoria* being the best. A class was also provided for a group of one hundred fine-foliage plants, but there was only one exhibitor—Messrs. Hooper & Co., Covent Garden, who were awarded the principal prize for a good collection of healthy *Dracænas*, *Yuccas*, *Pandanus*, Palms, and Ferns.

Ferns.—There was not a large display of Ferns, but in the amateurs' class for six specimens there were four entries, and the quality of the plants exhibited was very satisfactory. The best collection was contributed by Mr. C. Rann, the plants composing it, as in the fine-foliage

class, being noteworthy for their size. The three fine *Gleichenias*, which are so well known to frequenters of large metropolitan flower shows, were in excellent condition, being well furnished with young vigorous fronds; *Cyathea Dregei*, *C. Burkei*, and *Dicksonia antarctica* being also large and healthy. Mr. Child was a very close second; for although his plants were smaller than the first-named they were very neat, and could scarcely be excelled in freshness and vigour. *Phlebodium aureum*, 5 feet in diameter, had the fine characteristic glaucous tint well developed. *Microlepia hirta cristata* was similarly fine; and *Davallia Mooreana* was well represented. Mr. Douglas was third, staging good examples of *Gleichenias* and *Davallias*. The only nurseryman's collection was from Mr. B. S. Williams, who secured the first prize for specimens of medium size, but in clean vigorous condition. *Gleichenia flabellata* and *G. circinata*, with *Asplenium nidus*, were the most striking in the group.

#### GROUPS.

In every exhibition of more than ordinary extent the groups, whether arranged for effect or simply collections of plants, invariably constitute an important and attractive feature, the absence of which would detract considerably from the interest and completeness of the display; therefore it was satisfactory to see them so well represented at Kensington, where seven large and more or less handsome collections were contributed in the two classes devoted to them—namely, that for one hundred miscellaneous plants in bloom, and that for a group of the same number of plants in pots arranged for effect in a space not exceeding 300 square feet. The former were especially bright, and the premier collection from Messrs. B. Peed & Son was very greatly admired, as, though the plants were of moderate size, they were in excellent condition and flowering abundantly. All the principal useful and easily grown Heaths were represented by compact little specimens, plants of *Erica perspicua nana*, a neat dwarf variety that is much grown for market, being numerous. Many other greenhouse and hardwooded plants were also represented, *Pimeleas*, *Aphelaxes*, and *Azaleas* being shown in large numbers and vigorous health, while some small specimens of *Phœnocomia Barnesii* were noteworthy for their fresh healthy appearance. Messrs. Jackson and Son were second with a similarly bright group which, in addition to a large proportion of hardwooded plants, contained many well-grown *Pelargoniums* and *Orchids*. Messrs. Cutbush & Son were placed third with a neat group, in which *Dracophyllum gracile* and *Genetyllises* were largely shown in first-rate condition, and all the numerous other greenhouse plants included were flowering freely.

For the most effective group four competitors appeared, and though their contributions were diverse in style they were so nearly equal in merit that the Judges had not an easy task in determining their relative positions. Chief honours were, however, bestowed upon Mr. J. Aldous, Gloucester Road, South Kensington, who had a tasteful and attractive arrangement, though it was open to the objection of the smaller plants being rather too crowded. What may be termed the groundwork of the group was chiefly composed of *Fuchsias*, *Pelargoniums*, *Calceolarias*, and small Ferns, the effect being lightened by taller plants of *Lilies*, *Eucharises*, *Dracænas*, and *Palms* too regularly disposed over the group. The margin consisted of an outer line of variegated *Pelargoniums*, next to which was a border of *Caladium argyrites* alternate with small *Dracænas* and the white-flowered *Crassula jasminea* recently described in this Journal. Messrs. J. Laing & Co. followed with a less formal arrangement but rather weak in flowering plants, though *Rhodanthes*, *Gloxinias*, *Azaleas*, and *Spiræas* were freely employed. *Palms*, *Ferns*, and *Dracænas* were interspersed among the other plants, but chiefly formed a bold background. The third position was accorded to Messrs. Cutbush & Sons for a totally different group from the previous two, and if something better than the rather brown-coloured moss had been substituted for the groundwork it would probably have obtained a higher position. It was arranged on a sloping mound in one corner of the tent in a similar style to that shown by the same firm at the Royal Botanic Society's last Exhibition. At the back was a semicircular band of *Cordylines*, variegated *Maples*, *Azalea Souvenir de Prince Albert*, and *Abutilon vexillarium variegatum*; the ground thus enclosed being covered with moss, from which arose wooden stands supporting small Ferns, the base of each being surrounded by *Chrysanthemum frutescens* and other plants. But most notable in the group were the plants of *Erica Cavendishiana*, which though young were extremely vigorous, the branches being thickly clothed with unusually large richly coloured flowers. The largest specimens were in 8-inch pots, but smaller sizes were employed for the majority.

#### ROSES.

Although three classes were devoted to *Roses*, and liberal prizes were offered, only two exhibitors came forward; but the Cheshunt contributions were extremely fine, and thus compensated to some extent for deficiency in other respects. In the nurserymen's classes for twenty *Roses* in 10-inch pots and nine specimens, the size of pot unstipulated, Messrs. G. Paul & Son were the sole exhibitors, gaining the premier award in each. These specimens formed an imposing group on the slope near the chief entrance to the large tent, where their beauty could be seen to excellent advantage. The central plant of the large specimens was *Céline Forestier*, which has already been noticed several times this season: it was in fine condition, the foliage fresh and the blooms numerous. *La France*, too, was unusually fine

and well furnished with handsome blooms. Charles Lawson, Marie Rady, Anna Alexieff, and Francis Fontaine, all large and beautiful, also served to render the group one of the chief attractions of the Show. The smaller plants were arranged to form a margin to the others, and were in excellent health, bearing fine substantial blooms. Some of the varieties best represented were Mrs. Laxton, Abel Grand, François Michelin, Miss Ingram, and Camille Bernardin. Mr. Tranter, Upper Assenden, was the only amateur exhibitor, and gained the third prize for rather poor plants, which had evidently suffered considerably in their carriage to the Show.

#### PELARGONIUMS.

Admirers of Show and Fancy *Pelargoniums* would perhaps have desired their favourites to be more largely represented than was the case at this Show, but after making due allowance for the fact that it is still rather early in the season for these plants, the three chief collections staged were fairly satisfactory. Both classes were open, and in each nine specimens were required. Show varieties were represented by three collections, the best being that shown by Mr. J. Wiggins, gardener to H. Little, Esq., Uxbridge, in which the plants were very even, well grown, and carefully tied, the flowers being large and of excellent form. The beautiful varieties *Kingston Beauty*, *Rob Roy*, *Princess Alexandra*, and *Mary Hoyle* were especially vigorous and notable for the profusion of their flowers. Mr. C. Turner followed very closely with specimens little inferior to the preceding, the only observable deficiency being a slight degree of looseness and rather too prominent stakes. *Claribel* was admirably shown, *Emperor* and *Prince Leopold* being similarly beautiful. Mr. W. Griffin, gardener to J. Willcocks, Esq., Forest Hill, was third with small and rather rough specimens. In the class for Fancy varieties there were only two competitors, Mr. Wiggins easily securing the first prize with fine healthy plants flowering most freely, and including some very pretty varieties, of which the most noteworthy were *Lady Carrington* with neat flowers, pink and white, a delicate and charming variety; Mrs. Graham also very beautiful, the upper petals rich rosy pink, the lower white, flower large and of excellent form. *Princess of Teck*, *Ellen Beck*, and *Duchess of Edinburgh* were all handsome. Mr. Griffin was accorded the third prize for plants similar in quality to those in his other collection.

*Tuberous Begonias*.—For thirty *Tuberous Begonias* of not less than twenty varieties Messrs. J. Laing & Co., Forest Hill, staged a handsome collection of well-grown plants, representing many fine varieties, which well merited the premier prize that was awarded for them. One noteworthy feature of the group was the comparative small size of the pots employed, the largest not exceeding 8 inches in diameter, and as the plants were strong this imparted a light appearance to them which is too often wanting, excessively large pots being for these, as for other plants, not only injurious but far from ornamental. The flowers were generally of good size and fine colours, but in several instances the effects of travelling were observable. Some of the most effective varieties were *Robusta*, brilliant scarlet, large flower; *Lady Roberts*, soft scarlet; *Stanstead Rival*, salmon scarlet, very large well-formed flower; *Annie Laing*, a handsome pink variety of great substance, one of the best of its colour; *Miss Muir*, white tinged with pink, delicate; *Commodore Foot*, a dwarf compact form of the *Pearcei* type, with small but intensely dark scarlet flowers very freely produced; *Marquis of Salisbury*, a fine flower of a peculiar brilliant crimson tint; *Madame Huibelle*, bright salmon, very large; and *Pollie*, a good yellow variety. Mr. H. Coppin, Shirley, Croydon, was the only other exhibitor, and obtained the second prize for creditable plants, which were, however, in rather large pots. The varieties *Rêve d'Or*, yellow; *Orion*, soft scarlet; W. E. Gladstone, brilliant scarlet; *Salmon Queen*, and *Snowflake*, white, were some of the best, the blooms being single and of excellent form.

*Gloxinias*.—These were not largely shown, which is rather surprising, as they are so extensively grown. It is true they suffer considerably in transit to exhibitions, and often a promising collection at starting has a very different appearance when the plants reach their destination, but the prizes offered—namely, £4, £3, and £2, for thirty specimens might have been considered sufficient to encourage growers to compete. The chief collection was exhibited by Mr. T. Lyon, gardener to Sir E. H. Scott, Sundridge Park, Bromley, who had some well-grown plants bearing large flowers, particularly remarkable for the richness of the colours. Mr. W. Griffin was second with small examples. With the exception of the first-named collection, the best *Gloxinias* were in some of the groups and miscellaneous collections.

*Rhododendrons*.—In the class for twenty specimens Messrs. H. Lane & Son, Berkhamstead, contributed a fine group of these handsome plants, which on one of the mounds in the large tent produced an imposing effect. The plants were very compact and bore abundance of large trusses of flowers, the varieties being distinct and well selected for arrangement. Some of the most telling were *Lady Eleanor Cathcart*, soft salmon pink, neat truss; Mrs. John Waterer, bright clear pink; *Sidney Herbert*, mauve purple; Mr. J. Clutton, white; *Joseph Whitworth*, deep purplish crimson; *Exquisite*, white; *Sir Robert Peel*, rich crimson; and *Fastuosum flore-pleuro*, the peculiar lilac-coloured loose-trussed variety. Messrs. G. Paul and Son, Cheshunt, were second with tall standard plants of good varieties.

*Hollies*.—Messrs. W. Cutbush & Son, Highgate, were the only exhibitors of fifteen *Hollies*, and were awarded the principal prize for a

good selection of varieties, the plants being about 5 or 6 feet high, and the distinctive variegation fairly well developed. The most noteworthy were aurea regina, grandis, argentea marginata, Hodginsi, the useful dark green strong-growing variety for towns; angustifolia argentea marginata, media picta aurea, the silver Hedgehog, ferox argentea, Wateriana, Handsworthensis variegata, and Scotica, with very dark green smooth-edged leaves.

**Hardy Plants.**—Popular as hardy plants are now becoming, they do not at present rank very generally among exhibition plants, though at some of the northern shows the competition is often spirited and interesting. When several good collections are staged there is scarcely a more pleasing portion of an exhibition, owing to the diversity in their habits, flowers, and general appearance. At Kensington Mr. Douglas contributed the only collection of thirty hardy plants in pots, for which the second prize was awarded, but the Judges could scarcely have erred had they accorded it premier honours, considering its quality and the absence of any other competitors. Aquilegias were as usual very fine, the other chief plants being *Stenactis speciosa*, an elegant plant with Aster-like purplish or lilac flower heads; *Erigeron strigosus*, another ally of the Asters; *Lupinus bicolor*, flowers blue and white, very pretty; *Pyrethrum Gloire de Stella*, bright crimson; *Verbascum phœniceum*, with cream-coloured wax-like flowers; and *Spiræa palmata*, with its fine feathery trusses of rosy flowers.

**Cut Flowers.**—Two classes were appropriated to cut flowers, one for a group of hardy flowers in bunches, and the other for sixty blooms of Fancy Pansies, not more than two of each variety. In the first-named the only collection staged was from Messrs. Hooper and Co., who secured the chief award for fair examples of the scarlet Larkspur (*Delphinium nudicaule*), the pale yellow Globeflower (*Trollius europæus*), the large white-flowered Candytuft (*Iberis Tenoreana*), the Edelweiss (*Gnaphalium Leontopodium*), and others of less note. The best Pansy blooms were exhibited by Messrs. J. Cocker & Sons, Sunny Park, Aberdeen, who were placed first. The blooms were mostly of good size and substance but rather rough, the colours rich, and the varieties well selected. The third place in the same class was accorded to Mr. J. Lawrence, gardener to Mrs. O. Knox, Caversham, for neat blooms, but many of them much too small.

#### MISCELLANEOUS EXHIBITS.

These were numerous, and imparted much interest to the Exhibition, being chiefly contributions from nurserymen, generally of excellent quality, whether plants or flowers. At the end of the large tent, and facing the principal entrance, was a handsome group from the General Horticultural Company arranged in Mr. Wills's artistic manner, for which a gold medal was deservedly awarded. The background was composed of large Palms, the fore part of the group being occupied with a ground of Selaginellas and Adiantums, among which were fine Gloxinias, Odontoglossums, a central plant of *O. vexillarium* bearing large deeply coloured flowers, Caladiums, *Crassula jasminæa*, Tillandsias, Yuccas, the finely variegated form of *Cyperus laxus*, and the drooping Maidenhair Fern *Adiantum Bausei*. Several small Nepenthes were elevated on stands, while Crotons, Dracenas, and the elegant Pavetta borbonica also contributed to the beauty of the group. Most of the other collections that were not for competition were arranged in the long tent with the exception of ten boxes of fine Rose blooms from Mr. C. Turner, four remarkably well-grown Adiantums from Mr. Hawkins, florist, Bishop's Road, W., for which a bronze Banksian medal was awarded, and a plant of the fragrant *Philadelphus mexicanus* from Mr. Walker of Thame. Silver Banksian medals were awarded to the following exhibitors:—Messrs. B. S. Williams for a group of new and choice plants, chiefly fine-foliage plants, the new Ferns *Pteris internata* and *Actinopteris radiata australis* being especially noteworthy; Mr. C. Turner for a group of new Pelargoniums, Azaleas, and Carnations. A white single Azalea named Franklin was particularly noteworthy, the flowers being large and of symmetrical form. Pelargonium Martial, recently certificated, was also striking. E. J. Loder, Esq., 42, Grosvenor Square, for a collection of hardy Cacti which he had collected. Many varieties of *Opuntia*, *Echinocereus*, and *Pilocereus* were represented, several flowering; and to Messrs. Hooper & Co. for collections of hardy flowers and dried Grasses. A silver Flora medal was secured by Messrs. Barr & Sugden for groups of hardy plants and cut flowers; a bronze Banksian medal being awarded to Mr. H. Boller, Kensal New Town, for a large collection of Cacti.

Messrs. Kelway & Son, Langport, Somersetshire, exhibited boxes of double and single Pyrethrums, the single forms being very striking and in a great variety of colours, some being extremely rich, others soft. After the double varieties have had their day these singles will come in, and we shall be surprised if the demand for them does not come soon. A silver Banksian medal was awarded for them. Mr. T. S. Ware, Hale Farm Nurseries, contributed a very handsome collection of Pyrethrum blooms, both single and double, the colours being rich and the blooms large. They were highly commended. Messrs. H. Cannell & Sons, Swanley, also exhibited a stand of Pyrethrums of good varieties, and in excellent condition. Messrs. Osborn & Sons arranged a great collection of alpine and herbaceous plants, remarkable as well for the variety of the species as for attractiveness. *Czaekia liliago major* was very charming, and *C. liliastrium* elegant and stately. The *Cyclobothras* arrested attention, as also did the gorgeous Irises. A silver Banksian medal was awarded. Mr. J. L.

English, Epping, exhibited examples of Fungi, and garden and wild flowers preserved in their natural colours—a most successful instance of floral preservation. Mr. R. T. Veitch of Exeter staged a box of blooms of the old Devonensis Rose, which were magnificent, and as fragrant as fine. Messrs. Dick Radclyffe & Co. had dinner-table decorations, and an ornamental fernery and fountain at the entrance to the large tent. Mr. J. Aldous exhibited some table decorations and an elegant window box, and Messrs. James Cocker & Co. sent a collection of double Polyanthus and Pansies. In addition to these two groups were contributed from the Royal Horticultural Society's Gardens at Chiswick; one comprised a fine collection of Cape Pelargoniums, and the other was very elegantly arranged. *Adiantum gracillimum*, Gloxinias, and numerous plants of *Saxifraga nepalensis* imparting the distinctive features of the group, the tall panicles of the last-mentioned plant being particularly striking.

#### FRUIT.

Considering the number of entries a large display ought to have been provided, but as many failed to keep their engagements this department of the Show was only moderately furnished. The weather for several days immediately preceding the date of the Exhibition was surely bright enough and sufficiently warm for ripening fruit, and as it could have been sent with little expense there must have been some miscalculation in some respect, or the officials would not have been requested to reserve space and then have been put to the inconvenience of occupying it as they could. Notwithstanding, however, the disappointing shortcomings referred to the spread was the best that has been seen this year, and some very creditable examples of culture were staged.

#### PINES.

Four classes were provided for these, but in three of them only was there competition. Twelve fruits were staged, and with the exception of the two fine Smooth-leaved Cayennes from Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, South Molton, there was no exhibit of striking merit. The crowns of some examples were too large and others too small in proportion to the size of the fruit. In the open class for two fruits the pair above referred to distanced all others; one of these fruits weighed 6 lbs. and the other 6½ lbs. The second-prize pair from Mr. Child, Garbrand Hall, were medium-sized well-ripened Queens—closely followed, however, by a rather smaller pair, perfectly ripened, and with a due balance of fruits and crown, from Mr. Roberts of Gunnersbury Park. In the class for one Queen Mr. Roberts was first with a good fruit; Mr. Sage, Ashridge Park, being second with a plump crownless example, and Mr. Child third with crown enough for two. In the class for any other variety the prizes went respectively to Mr. Miles, gardener to Lord Carrington, for Charlotte Rothschild; Mr. Bates, gardener to J. E. Meek, Esq., Poulett Lodge, Twickenham, with Prince Albert; and Mr. J. E. Muddell, Moor Park Gardens, Rickmansworth, with Black Jamaica.

#### GRAPES.

**Black Grapes.**—There were six collections in the open class for three bunches of Black Hamburgs, the examples from Mr. Loudon, gardener to T. Barnes, Esq., The Quinta, Chirk, overweighing the others completely. The bunches were very large and full, the berries being excellent and fairly finished. The central bunch apparently weighed about 5 lbs., and the exhibit was greatly and deservedly admired. Mr. Fyfe, gardener to W. W. Dick, Esq., Thames Ditton House, was second with small bunches; and Mr. Phillips, gardener to Capt. Jackson, The Deodars, Meopham, third with rather loose bunches, and the best finished berries in the Show, but small.

For three bunches of any other black variety Mr. Bolton, gardener to W. Spottiswoode, Esq., Combe Bank, Sevenoaks, was an excellent first with remarkably fine examples of Black Prince; Mr. Mowbray, gardener to the Earl of Leven and Melville, Fulmer, Slough, a good second with the same variety.

**White Grapes.**—Mr. Loudon secured the first honours with Muscats; bunches medium, berries fine, but not quite ripe. Mr. Maher, gardener to C. Allhusen, Esq., Stoke Court, Slough, was second with loose bunches. In the Any other white class, Mr. Mowbray secured the foremost place with Buckland Sweetwater of excellent quality; berries very even and good, but bunches not large. Mr. Aslett, gardener to C. Butler, Esq., Warren Wood, Hatfield, was an excellent second with very good Foster's Seedling, but not quite ripe; and Mr. Bolton third with the same variety, also unripe.

#### PEACHES AND NECTARINES.

**Peaches.**—Eight dishes were staged of average quality, but the larger fruits especially were deficient in colour. The first-prize dish from Mr. Crump, gardener to the Duke of Marlborough, Blenheim, was certainly the finest, the variety being Grosse Mignonne. Mr. Hinds, The Gardens, Canford Manor, was a close second with Royal George, very well coloured; and Mr. Lockie, gardener to Lord Otho Fitzgerald, Oakley Court, Windsor, third with apparently Grosse Mignonne.

**Nectarines.**—The first-prize dish of Lord Napier, very fine, came from Mr. Holliday, gardener to J. Norris, Esq., Castle Hill, Bletchingley; Mr. Nash, gardener to Mr. Fuller, New Shoreham, Sussex, being a good second with Stanwick Elruge.

**Cherries.**—Six dishes were staged, the Black Circassians from Mr. Miles being wonderfully fine. This exhibitor easily won the

first prize in both classes. Mr. James Read, Moat Mount, Mill Hill, was second in the class for two dishes, and Mr. Austen, Ashton Court, Bristol, had the same position in the single-dish class.

**STRAWBERRIES.**—These were good, if not grand; yet the first-prize dishes of Sir Charles Napier, Sir J. Paxton, and President from Mr. Norman, The Gardens, Hatfield, were very superior, good in size, brilliant in colour, and in fine condition. The exhibitor uses Clay's fertiliser for Strawberries, and certainly not without effect. The second prize went to Mr. Goldsmith, The Gardens, Hollenden Park, Tonbridge; and third to Mr. Worthing, gardener to A. Moss, Esq., Chadwell Heath, Essex, but the fruits were rather overripe. Mr. Mortimer, gardener to Major Storer, Purley Park, Reading, was first in the single-dish class with President, very highly coloured; Mr. Worthing, second; and Mr. Norman, third, all with President.

**MELONS.**—About thirty fruits were staged, some being large and several handsomely netted; and although most of them were of fair quality, a few were deficient in flavour. Mr. Miles, Wycombe Abbey, was distinctly ahead of his rivals with a fine fruit of Golden Gem, very juicy and delicious; flesh nearly white. Mr. Lockie was second, and Mr. Goldsmith, Hollenden, third, both with Hero of Lockinge.

**TOMATOES.**—Six dishes were staged, all the fruit being highly creditable to the cultivators. The first-prize dish of Stamfordian from Mr. Ward, gardener to the Earl of Radnor, Langford Castle, Salisbury, was very fine. Mr. Bones, gardener to D. McIntosh, Esq., Havering Park, Romford, was second with Acme, very good; and Mr. Austen was a very close third with excellent examples of Orangefield.

**MESSRS. BOYD'S PRIZE.**—For six dishes of fruit, distinct, Mr. L. J. Baker, Haddon Hall, Eastcote, Pinner, was the only exhibitor, staging a very small Pine, medium Grapes, good Figs, a Melon, and Peaches, thus securing the silver cup as easily as any similar trophy was ever obtained.

#### MESSRS. SUTTON & SONS' PRIZES.

There was excellent competition in the class for two kinds of Melons and two of Cucumbers, and splendid produce was staged by a dozen or more exhibitors. The first prize, £5 5s. or a gold medal, was won by Mr. Lockie with almost perfect fruits of Hero of Lockinge and Hero of Bath Melons, and Suttons' Duke of Connaught and their Improved Telegraph Cucumbers. Mr. Mann, The Gardens, St. Vincent's, Grantham, followed, securing the silver medal with a weighty collection, Hero of Lockinge Melon being very fine. Mr. Goldsmith of Hollenden was a good third; Mr. Atkins, Lockinge Park, fourth; and Mr. Howe, Benham Park, fifth. This class formed a fine feature of the Show; it afforded much satisfaction to spectators, and reflected credit alike on Messrs. Suttons and their skilled clients.

**MISCELLANEOUS.**—Mr. Sage, Ashridge, exhibited a magnificent bunch of Bananas, weighing 98 lbs., one of the finest examples of culture that has ever been staged at an exhibition, and a valuable contribution to this section of the Show. A silver Banksian medal was awarded for it. Mr. Wells, Earlswood Nurseries, Redhill, staged good examples of his Improved Telegraph Cucumber; and Mr. Goldsmith exhibited twelve Melons not for competition—a most worthy contribution.

#### VEGETABLES.

Five excellent collections were staged in the class for ten dishes, distinct kinds, and Mr. Austen had the great honour of placing Mr. Miles in the second position. The dishes comprised a splendid bundle of Asparagus, superior Stamfordian Tomatoes, excellent Crook's Walnut-leaf Potatoes, wonderfully fine Vegetable Marrows for the season, very fine Early Munich Turnips and French Beans, and good Carrots, Cucumbers, Peas, and fair Cauliflowers. Mr. Miles, however, followed closely; his best dishes, those that were superior to Mr. Austin's, being Laxton's Unique Peas, Cucumbers, and Carrots, and some others were equal. There was much discussion on the awards, but after a critical examination we considered that Mr. Austen won by two points, and afterwards found that the Judges arrived at precisely the same decision. Mr. Ward, Longford Castle, secured the third prize.

Prizes were offered by Messrs. Sutton & Sons for four dishes of Peas; Mr. Ward, Longford Castle, securing the silver medal with excellent dishes of Ringleader, First and Best, Emerald Gem, and William I. Mr. Chettleborough, Wanstead House, Norwich, having the second prize, a bronze medal, with Dillistone's Improved, Excelsior, William I., and American Wonder, the pods being larger but not so full as the first-prize dishes.

#### IMPLEMENTS AND APPLIANCES.

Under this heading are included horticultural structures, boilers, machines, tents, seats, wirework, engines, pottery, rustic adornments, cutlery, instruments—indeed every requisite connected with the garden. Thus a large field was opened for a great display; and the importance of the department was recognised by the offer of thirty medals, two of gold, and fourteen each of silver and bronze. The response of inventors and manufacturers was commensurate with the inducements offered for their enterprise; and what may be termed the mechanical section, it will be no exaggeration to say, was the most prominent feature of the Show. There have been on the whole finer plants at South Kensington, more and better fruit, and a greater display of vegetables, but never such an extensive, valuable, and varied collection of the nature as the one under notice. The exhibits apparent covered from two to three acres of ground, and the Judges had such

a task in examining them and determining the respective merits of the almost bewildering assortment of articles that they are not likely soon to forget; for Sir Henry Strickland, Bart., Mr. Shirley Hibberd, and Mr. Stevens of Trentham appeared to be engaged the whole of the first day and until noon on the second before they completed their difficult task. Following the order of the classes we commence with

**Garden Cutlery.**—The old and eminent firm of Messrs. Saynor, Cooke, & Ridal of Sheffield easily won the silver medal with an extensive assortment of knives and edge tools of all descriptions, highly finished and artistically arranged. The Standard Manufacturing Company, Derby, also exhibited a new fruit-gatherer, which is extremely light, and severs the fruit from branches which cannot be reached by ladders and collects it into a net. The mechanism of the implement is very satisfactory. A certificate of merit was granted. The bronze medal did not appear to have been awarded.

**Pottery.**—The Judges had no difficulty in this class, for a glance was sufficient to show that the exhibit of Mr. John Matthews of the Royal Pottery, Weston-super-Mare, overpowered all others, and the silver medal was awarded to a multifarious assortment of articles, useful, durable, and artistic, including flower pots of all sizes, vases, window boxes, rustic ornaments, plant protectors, indeed about everything of service in the garden that is wrought by the potter's skill. Messrs. Dick Radclyffe showed useful articles in this class, as also did Messrs. Doulton & Co. of Lambeth, whose window boxes especially we thought deserving of official recognition. They were not only of good appearance and durable, but were made in sections of about 6 inches square, any number of which placed together forms a continuous box, apparently in a solid piece; thus, a sill of any size can be furnished, or a number of separate square pots be utilised.

**Garden Tools.**—Messrs. Nettlefold & Sons, High Holborn, London, were successful in securing the silver medal with a large and varied collection of articles for almost every purpose of the garden, strong, well finished, and of excellent quality, including the Coventry lawn mower, which appears strong, simple, and durable; hose reels, water barrows, rollers, &c., besides hand tools of all kinds, and capital mat, garden, and hall scrapers—a collection of great utility. Mr. Thornton, Turnham Green, was awarded the bronze medal for a varied collection of garden tools of approved pattern, strong, handy, and well finished, such as find favour in a great and critical market-gardening district. The standard tree pruner of the Standard Manufacturing Company was exhibited in this class; the manager brought a large tree to operate on, and was able to show highly satisfactory work. A certificate of merit was awarded to this implement, which was figured in our columns, vol. xxxvii., page 172.

**Wirework.**—Of this the display was very extensive and of great excellence. The silver medal was secured by Messrs. J. J. Thomas and Co. of Edgware Road, London, for splendid examples of workmanship, including flower stands and baskets, trellises of all forms and sizes, arches, bordering, fencing, aviaries chaste in design and of various sizes, with numerous other articles which combined ornament with utility in a remarkable manner—a most valuable contribution. Mr. Holliday of Chelsea was awarded the bronze medal with an assortment of strong and well-constructed articles that merited the approval that was accorded them. Messrs. Wrinch & Son, Norwich, Messrs. T. Green & Son, and Dick Radclyffe & Co. also exhibited sound and well-made articles in wirework among sundry other exhibits of value, showing taste in design and good workmanship.

**Garden Seats, Chairs, &c.**—An enormous number of these were on view, the contributions of about half a score of exhibitors, all of whom submitted excellent productions. The silver medal was awarded to the celebrated firm of Boulton & Paul, Norwich, for a remarkable display, showing great variety in form, good materials and workmanship, and superior finish. Messrs. J. J. Thomas & Co. closely followed with a most meritorious collection of articles, and deservedly secured the bronze medal. The Panklibanon Furnishing Ironmongery Company, Messrs. Nettlefold & Son, T. Green & Son, Dick Radclyffe, and A. McLaren & Co. exhibited well in this class, their articles bearing the stamp of good quality.

**Meteorological Instruments.**—The silver medal was awarded to Messrs. Joseph Davis & Co. of Kennington Park Road for a display of great diversity and high finish. Barometers, thermometers, hygrometers, and other instruments were represented in various forms. Instruments of the same nature were also included in the great miscellaneous exhibits of Messrs. Corry, Soper & Co., and Dick Radclyffe & Co.

**Flower Stand, Vases, Window Boxes, &c.**—Messrs. J. J. Thomas and Co. were once more successful in securing the silver medal. The articles, which were numerous, showed great fertility in design, and combined elegance with strength. Messrs. Dick Radclyffe's contribution, which was adjudged the bronze medal, contained well-constructed and finished articles for various purposes and positions. The Panklibanon Co. also exhibited articles of great merit.

**Tenting and Shading Materials.**—The contributions in this class made an imposing display, as may be expected when the great firms of Mr. Benjamin Edgington and Mr. J. Unite put forth their strength. The first-named exhibitor secured the silver medal with a valuable contribution, including tents of various shapes, including the simple and very useful umbrella garden tent, awnings for chairs, and shading and protective materials of the different kinds that are used in gardens.

Mr. Unite had the bronze medal with articles of the same nature. Mr. W. Cains, Poole, was worthily awarded a certificate of merit for a small and very useful garden tent, showing much ingenuity on the part of the inventor. The tent is 7 feet by 5 feet, has no central pole, yet is strong and rigid. The tent contains a seat and table, which at the first glance would seem to serve no other purpose than the ordinary one; but they do, for they are so constructed as to form a box into which the tent and its paraphernalia can be packed; the box being only 3 feet long, 18 inches wide, and 9 inches deep. Mr. Cain has further carried his ingenuity to the top of the tent, for the central ornament is the mallet for fixing the pegs. This tent ought to be a treasure to picnickers, and is suitable for small lawns generally. Messrs. Boulton & Paul, J. J. Thomas, and Dick Radclyffe had many articles in this class, not less useful than those above mentioned.

**Mowing Machines.**—The Judges' work in this class of eight exhibitors, each having a number of machines, was no sinecure, for special advantages in some form or other were claimed for each kind of mower; and it may be safely said that all were good and did their work well. After a critical examination the silver medal was granted to the old firm of world-wide fame, Messrs. T. Green & Sons of Leeds and London. As the machines are known in all lands where good lawns are cherished it is quite unnecessary to give any description of them. The bronze medal went to Messrs. Ransomes, Head, and Jefferies for a remarkably good method of delivering grass from the boxes of the machines worked by horse power. This is a most efficient contrivance that will commend itself to all operators; the machine is also strong in make, easily worked, and cuts smoothly.

Messrs. Samuelson, Banbury, had a number of machines suitable for the smallest as well the largest lawns that did their work well. Mr. T. Clark (Chadborn & Coldwell Manufacturing Company) was awarded a certificate of merit for the Excelsior machine that won the silver medal last year. It is simple in design, strong, and works with great smoothness and ease.

**Garden Engines, Syringes, &c.**—There was much competition in this class. Messrs. Boulton & Paul were successful in securing the silver and Messrs. Arnold & Sons the bronze medal. The Norwich collection was an extensive one, and included a great variety of appliances for distributing water in the open air and under glass, in large gardens and in small, and was altogether a most meritorious collection. Messrs. Arnold, besides showing hand syringes, had the efficient "Simplex" pump figured and described in this Journal last year, page 169, vol. i., new series. Mr. J. Deverill, jun., Slough, was adjudged a certificate of merit for his patent irrigator for watering lawns. Considerable ingenuity appears to have been displayed in its production, and the Judges' approval was given after seeing it in operation. It is self-acting, and attracted much attention from visitors.

**Rustic Adornments.**—Mr. J. C. Fox of South Kensington, whose summer-houses are so widely known and in such high repute, received the silver medal in this class for a number of picturesque structures of different sizes and patterns, and adapted for the adornment of gardens and pleasure grounds of various sizes and character. They are most satisfactory works of their kind—substantial, and of that quaint and pleasing appearance that commend them to those

Fig. 104.—FOSTER & PEARSON'S SILVER MEDAL TENANT RIGHT STRUCTURE.

who require houses of this nature. Messrs. Dick Radclyffe & Co. were adjudged the bronze medal in this class for tasteful constructions of the same character.

**Heating Apparatus.**—A great number of boilers, valves, &c., were exhibited by eight competitors, and considerable interest was manifested in the verdict of the Judges, and much discussion was brought to bear on the merits and shortcomings of the different boilers. The apparatus for which the silver medal was awarded was a wrought iron saddle boiler with a series of intersecting tubes, somewhat in the form of the letter X, but the tubes in ogee form, in the crown of the boiler. Most gardeners who examined the boiler expressed a favourable opinion of it, but some thought there was scarcely sufficient space for fuel for what is known as "banking-up." It is no doubt a quick and powerful boiler without being complex, the latter condition having, no doubt, had weight with the Judges. The bronze medal was won by Mr. Warhurst of Highgate for an apparatus designated "Ben's Boiler," a ribbed and flued saddle, the flues being in the sides, and the ribs, in the form of teeth, in the crown; there is also a cross connection in the arch between the two ribs or teeth, and from this cross piece a vertical waterway to the crown of the boiler, affording a free passage of water to the flow pipe. This appears to be a strong and useful apparatus, and will probably do its work well. Mr. Wagstaff had vertical and arched tubular boilers; and Mr. Watson saddle and wedge, also suspension boilers, which found favour with some on-lookers, but as a rule the Judges' decisions were acquiesced in by the horticultural public. Several boilers were included in the miscellaneous collections of other exhibitors. Messrs. Weeks & Co. exhibited their well-known, widely used, and much-approved tubular boiler, but not for competition, also models of horticultural structures of the various kinds as made at their works at Chelsea.

**Garden Structures Modes of Glazing, &c.**—There were no less than seventeen competitors in this class, and the exhibits covered a great amount of space. The silver medal was awarded to Messrs. Foster and

Pearson of Beeston, Notts, with portable frames that were awarded the silver medal last year, and figured and described on page 493, vol. xxxviii.; also a fine span-roofed greenhouse represented in the annexed engraving. It was for this house that the medal was given. It is not only a fine house, 40 feet by 18 feet, strong, with grooved rafters to prevent drip, elliptically cut glass to prevent the putty being saturated and thoroughly ventilated; but it is a true tenant's structure, and can be removed at will. Of this there is no doubt. It can be taken down quickly without disturbing the glass, and speedily erected again as may be necessary. It is also equally a landlord's structure, as owing to the width of the iron foundation standards, 3 feet, the structure is firm and immovable by the wind. The sides are bounded from the ground to stage. It is a substantial and useful house for plant or fruit culture, and worthy of the honour it has received. The bronze medal was adjudged to Mr. Helliwell of Brighouse, Yorkshire, and Parliament Street, London. This is a well-proved system of glazing without putty, all the woodwork being covered with glass, the squares being securely fixed by lead clips on horizontal sashbars; the bars are channelled for the prevention of drip, and the roof may be fairly described as firm, safe, simple and effectual. Certificates of merit were granted to Mr. C. Causley of West Hackney; to Messrs. Tracey & Son, Ilford; to Messrs. Johnson Brothers & Co., Waterloo Place, Pall Mall, and to Mr. T. Bickley, Birmingham, for systems of glazing without putty. Mr. Causley's method is applicable to ordinary sashbars, which are here covered with metal caps, between which and a metal lid in the rebate the glass is inserted and securely gripped. The roof is strong, light, and waterproof, and means are adopted for preventing drip by condensed moisture. Messrs. Tracey's plan consists of tubular metal sashbars with longitudinal slits, in which the glass is inserted and held securely, the tubes resting on horizontal sashbars the same distance apart as the squares are in length. A noticeable feature in this plan is its great simplicity; the roof is curvilinear. Messrs. Johnson's

method is of the same nature as Mr. Causley's, yet is essentially distinct from it, and is good, the roof being quite firm, the glass safe, and no drip from rain nor condensed moisture. The same firm also exhibited their moveable glass coping for protecting wall trees when needed, and admitting the rain or night dews to them as required. The protectors are worked with a crank, and are perfectly safe from injury by wind in whatever position they are placed. The entire arrangement is strong yet light, and works with ease and smoothness. Mr. Bickley's method is of the same character as Helliwell's, inasmuch as the entire framework of the roof is covered with glass, but the method of fixing is different, and a light, firm, and durable roof is produced. In this class also Messrs. Boulton & Paul exhibited a conservatory and a capital assortment of garden frames; Mr. Warhurst, a three-quarter-span greenhouse showing the Paxton roofs and ventilators in different forms, glass copings, concrete slabs for walls, flooring, stages, &c.; Mr. S. E. Wheeler, Nottingham, a span-roof greenhouse with improved ridge lift ventilation and simultaneous side ventilation, and a lean-to house called "The Nottingham;" Mr. H. Beare, Newton Abbots, Devon, handlights, the glass affixed in zinc; Mr. W. Howitt, Ilford, a small greenhouse showing still another new mode of glazing; Fletcher, Lowndes, & Co., specimens of glazing for roofs, conservatories, &c., without putty which have been fully described and illustrated on page 169 of this volume; Messrs. Rosser & Russell, conservatory, greenhouse, and patent system of glazing without putty; Mr. Henry Hope, Birmingham, a metallic vinery, iron conservatory, iron staging and valves and wood, iron tree covers glazed without putty—a substantial exhibit; Mr. T. C. Humphreys, 15, Albert Gate, S.W., iron building suitable for gardener's or labourer's cottage, fruit garden or summer-house, with galvanised corrugated iron roofing; and Messrs. W. Lawrence & Son, Datchworth, showed a small greenhouse with improved system of glazing.

*Miscellaneous Exhibits.*—This class was formed for articles not included in the above classes, and the chief exhibitors were Messrs. Dick Radclyffe & Co., who secured the silver medal for rockeries, fountains, porcelain flowers, table conservatory, Fern case, &c.; these, added to their collection of garden requisites, made a very extensive and diversified display. The bronze medal was worthily awarded to Messrs. Corry, Soper, Fowler & Co., Finsbury Street, E.C., of nicotine soap fame; but they had much more than nicotine soap and other insecticides, fertilisers, &c., for they had a most complete and attractive stand in the corridor. It contained an example, and a good one, of almost every article used in the garden, and was undoubtedly a contribution of very great merit. A certificate of merit was awarded for the Pall Mall edge cutter (Adie's Patent) which was figured and described on page 151 of the present volume; and Messrs. Soan and Smith, Oxford Street, and Messrs. Batham & Co., Bond Street, London, were highly commended for flower glasses and china. The following exhibitors also had stands:—Messrs. Boulton & Paul, a great assortment of miscellaneous articles; Messrs. Kessell & Son, Southwark Street, patent anti-pneumatic fountains for conservatories; Messrs. Morris & Griffin, Wolverhampton, packages of Florein, Daisy destroyer, disinfecting powder, &c.; Mr. W. Speed, The Gardens, Penrhyn Castle, Bangor, nursery and garden slate labels; Messrs. Stevens & Pinches, their "Acme" labels that are so largely used now; Mr. W. Wells, Earlswood Nurseries, Red Hill, a new spray-distributor likely to prove useful for the application of insecticides; Mr. W. Clark, Oxford Street, grass and turf cutters—novel and useful; Mr. A. Westwood, Kirkwood Road, Nunhead, garden labels; Mr. Laxton, Bedford, Rose hook for the removal of Rose suckers; Mr. T. Edington, The Gardens, Woodthorpe Grange, Nottingham, labels; and Messrs. W. P. & G. Phillips, Oxford Street, china and glass, not for competition.

*GOLD MEDAL EXHIBITS.*—After the awards were made in the various classes the task devolved upon the Judges of determining the merits of the collective displays of the several exhibitors, with the view of granting two gold medals for the largest and most meritorious contributions. These proved to be those of Messrs. Boulton and Paul and J. J. Thomas, both of whom had most extensive, diversified and magnificent displays. The mere enumeration of the articles would require so much space that instead of publishing a list we recommend those who are interested to send for the catalogues of the exhibitors, and as almost everything in them was represented at the Show an idea may be formed of the extent of the collections.

A Show of such magnitude as this necessarily demands the exercise of much judgment on the part of the officials, and close attention to the various details on which the success or failure of such meetings to a great extent depend. At South Kensington the officials are adepts in their work, and all work harmoniously and with the same object—namely, of rendering the gatherings as successful as possible and agreeable to all. For these efforts so assiduously rendered a meed of recognition is justly due to all who share in the work of such a great undertaking, and our mite is readily accorded.

*NEW AND OLD PEACH TREE TRAINING.*—Mr. Simpson referring to this subject (see page 438) is wrong in saying I did not give the size of the trees when planted. I said on page 327, "The trees were young, clean, and vigorous, and had, at the time of planting, from three to five well-ripened shoots, each of one years' growth." The crop of 112 dozen was gathered in one, and

not in three years. I admit the correctness of Mr. Simpson's remark about our ages. When I used the expression referred to I meant to convey that I was in possession of facts that the system had been practised for more than fifty years. This finishes the above discussion as far as I am concerned.—A. PETTIGREW, *Castle Gardens, Cardiff.*

#### HYLANDS PARK GARDENS.

A FEW weeks back I visited the gardens at Hylands Park, Chelmsford, the seat of Arthur Pryor, Esq., and if a convincing proof is wanted, there is one of the advantages to be derived from allowing Peach trees to grow unrestricted. Some young Peach trees only planted last year in a house had completely filled the trellis; one tree in particular (I think a Noblesse) had made more growth than any of the others, and its stem was larger than any that I have ever seen for its age. Mr. Bowman is a great advocate for abundance of foliage in all cases, and his opinion is well substantiated by the results. Grapes receive free treatment, and the effect is very satisfactory; about three years back some Muscats were lifted in November, the border re-made, and the results are most pleasing. Mr. Bowman has also paid great attention to the fruit trees, having removed all the old trees and planted others against the walls and lines of pyramidal trees, all of which are doing well. Osborn's Prolific Fig in pots was grand, the branches being staked to hold up the weight of fruit. Strawberries were good and in abundance, two houses being devoted to them. Melons were also very good, the majority being ripe or ripening. Pines, Cucumbers, and all in the fruit houses, of which there are sixteen, looking remarkably well. Just at the season when I was there the flower garden was a grand feature, all the beds being filled with spring-blooming plants. Belvoir Castle and Tom Thumb Wallflowers in thousands; *Myosotis dissitiflora* the same; Daisies pied and *Violas* blue, also in thousands; *Silene compacta* in noble masses; and *Aubrietia purpurea* was most effective. An herbaceous border planted recently contained some fine plants, and will make a pretty margin to the boundary of the flower garden. In nearly the centre of the flower garden stands a fine conservatory, which is composed of three compartments—stove, intermediate house, and greenhouse—well filled with decorative plants grown in other houses in the same garden, which is important in a large establishment like Hylands. The most remarkable plants were *Bougainvillea glabra* and *Lapageria alba*, the *Bougainvillea* with extremely fine branches 2 feet in length, and bearing upwards of two hundred flowers hanging loosely from the roof. But where there is so much done well it is almost an impossibility to particularise. The fine park, mansion, flower and kitchen garden are well worthy a visit, and a courteous reception will be given to any true lover of gardening who should happen to call on Mr. Bowman, the able and energetic gardener and manager.—J. G.

DURING the past week the action brought by Her Majesty's Commissioners of the Exhibition of 1851 against the ROYAL HORTICULTURAL SOCIETY has been before Mr. Justice Fry in the Chancery division, for the recovery of the Garden at South Kensington. The case on behalf of the plaintiffs was stated by Mr. North, Q.C., and that for the defendants by Mr. Fisher, Q.C. The debenture-holders, who claim an indemnity from the Royal Commissioners, are represented by Mr. Montague Cookson. Long arguments have been presented to the Court on each side, but as the case of the debenture-holders was not closed when the Court rose for the Whitsun holidays, it will be resumed on Tuesday the 14th inst.

— A CORRESPONDENT informs us that the unusual severity of the past winter has been felt most forcibly at Lambton Castle, Mr. Hunter having already cut over three hundred cartloads of dead wood from the shrubs. Many of the hardy spring bedding plants have also suffered considerably; the exception to this, however, being *Valeriana Phu aurea*, which has passed scathless,

proving invaluable for spring bedding, and most effective associated with Aubrietias.

— IN the same garden the STANDARD MORELLO CHERRIES are proved to be a decided acquisition, and will in future be extensively grown, as during the past year they have borne heavy crops and ripened the fruit well.

— JUST on the eve of going to press we learn that the following are the approximate numbers of visitors to the ROYAL HORTICULTURAL SOCIETY'S SHOW exclusive of Fellows; and the results show the deterrent influence of the unfavourable weather on the two popular days, Monday and Tuesday. Friday, 1288; Saturday, 1610; Monday, 3632; and Tuesday, 2200: making a total of 8730.

— WE have received a copy of a revised edition of the "SCHOOL GARDEN" by Mr. T. Wilkinson, the original issue of which has been already referred to in these pages. The present edition is slightly enlarged and modified in various ways, but in other respects it is precisely similar to the first edition. It is published at the Gazette Office, Harrow.

— TWO of the most attractive occupants of our shrubberies at the present time are *HALESIA TETRAPTERA* and *EXOCHORDA GRANDIFLORA*, both of which have been figured in this Journal, the former in vol. xxxvi., page 481, and the latter in vol. xxxvii., page 71. These trees are not so well known as they deserve to be, for they are scarcely rivalled as ornamental flowering trees, their value being increased by the fact that they are (especially near London) in their most attractive condition just as the species and varieties of *Pyrus*, *Cerasus*, and allied genera which contribute so much to the adornment of our gardens, are losing their flowers. The scarlet varieties of Hawthorn are, however, excellent companions for the two named, the brilliant colour of the former's flowers contrasting well with the pure white pendulous Snowdrop-like flowers of the *Halesia*, and the large, open, pearly-white blossoms of the *Exochorda*. The Snowdrop Tree and the Pearl Bush are the elegant popular names by which these plants are respectively known.

— THE last issue of "L'Illustration Horticole" contains an engraving representing a BASKET OF ORCHID FLOWERS which was presented by the "Chambre Syndicate des Horticulteurs Beligues," to Princess Stephanie on the occasion of her marriage with Prince Rudolph. The basket was extremely elegant in design, rather more than a yard in height, and about 32 inches in breadth, being entirely filled with Orchid flowers of the choicest and most diverse kinds. They were very tastefully and informally arranged, so that they drooped gracefully over the sides of the basket, some being twined around the high arching but slender handle. They were secured from fading by a foundation of Ferns being placed in the basket, among which small phials of water were hidden, and in these the stalks of the flowers were inserted. Although, as may be imagined from the size of the basket, a large quantity of flowers were required, it is said that quite four times as many as were needed were forwarded to the Committee. This novel and handsome present was greatly admired by the Royal recipient.

— A CORRESPONDENT writes as follows on the SMALL CASE-BEARING LARVA ON ROSE as referred to by Mr. Lester on page 393. "We have not seen this alive, but presume the species is the *Coleophora rosacella* of some authors. The larva constructs a horn-like granulated case out of the leaves upon which it feeds, occurring upon the Rose, generally in April and May. A much larger case-bearer has been taken on this plant, particularly in the west of London. This is the grub of the Rose eaddis fly (*Lyda inanita*), which travels from leaf to leaf, disfiguring the plant, and it attains the length of nearly an inch. The season for

this species, however, is the month of July. For either of these there can be no remedy save the tedious one of hand-picking."

— A PLANT of the peculiar *ARISTOLOCHIA GOLDIEANA* has recently produced several flowers in one of the houses in the gardens of the Royal Botanic Society, Regent's Park. An engraving and full description of this extraordinary plant appeared in vol. xxxviii. of this Journal, page 456. This is said to be the third time the species has produced flowers in Great Britain.

— WE are requested to remind our readers that the SCOTTISH PANSY SOCIETY'S SHOW will be held in Edinburgh on the 17th inst., and as no notice is required from competitors the Committee hope that southern exhibitors will enter the lists. We are informed that the plants in Scotland, owing to the cold season, having as yet made but little growth, the flowers are not in their usual good condition.

— A CORRESPONDENT, "G. F.," writes as follows on the NIGHT-BLOOMING CEREUS:—"Last evening, June 5th, I had the first bloom this year on my plant of the Night-blooming Cereus, *C. grandiflorus*. There are twenty-one buds still to open. Although this plant usually yields a number of blooms, I do not think I ever remember quite so many before. The flower at 9:30 P.M. measured about 2 feet in circumference, the centre 4 inches in diameter. Its scent, which is just like Vanilla, was quite overpowering, and I had to remove the flower from the room in which I was sitting."

— WE are sorry to have to announce the death of Mr. JOHN SANGSTER, formerly a partner in the old seed house of Hay, Anderson, & Sangster, which was flourishing at Newington Butts in Surrey a century ago. The business was established by Walter Hay, a native of Aberdeen, about the middle of the last century; and he was succeeded at his death by his brother, Mr. John Hay, who by his ability raised the house to one of high standing in the seed trade. At his death Mr. John Hay was succeeded by his nephew, Mr. J. Anderson; and Mr. Sangster, who was formerly in business at Aberdeen, having married Mr. Anderson's sister, was admitted a partner of the house. After the death of Mr. John Hay the business lost its guiding spirit; and though Mr. Sangster devoted his best energies to carry it on successfully he failed in doing so, and ultimately, yielding to the force of circumstances, he was compelled to retire without having any provision against the requirements of old age. Mr. Sangster took an active part in the formation of the Gardeners' Royal Benevolent Institution, and was one of the first ten-guinea life members. For many years he took a leading part in its management, and ultimately he was forced to become a pensioner on its funds—a boon which he gratefully received for upwards of eighteen years. It may not be generally known that Mr. Sangster was the raiser of the early Pea called Sangster's No. 1. The writer of this remembers seeing it at the nursery in St. George's Fields about the year 1846, when the whole stock consisted of a single row about 4 yards long. It was selected from a variety then known by the name of Cormack's Prince Albert, which in its turn had been selected from the old Early May. For several years the seed was saved in the nursery, and when the stock amounted to some bushels it was sold retail at half-a-crown a quart. Soon after it was sent out a portion of the stock fell into the hands of Mr. Waite, a seedsman who, it was said, was fortunate in a race won by a horse called Daniel O'Rourke at Epsom, and he sent out the Pea under that name. The true Sangster's No. 1 is difficult now to be obtained, many other names doing duty for it in the seedsmen's catalogue, and the nearest approach to it in its true form is that known as Dillistone's Early. An experiment which he conducted on rather a large scale was to raise early Potatoes from cuttings of the young spires in the hope of thereby avoiding

the Potato disease. At first the results he obtained were encouraging, and it was thought that a remedy had at last been obtained against the disease; but these hopes were dispelled, and it was found that Potatoes raised in this way were as liable to the attacks as those raised after the ordinary method. Mr. Sangster died on the 27th of May in the eighty-fifth year of his age, at Romford in Essex, where he lived for many years.

#### FRUIT PROSPECTS, 1881.

IN this neighbourhood (Brentwood) the fruit crop promises to be but partial. Gooseberries fair, Currants abundant, Raspberries fair, many canes dead; Strawberries looking well, but early blooms were killed by frost; Plums a light crop; Damsons very scarce; Apples on bush trees thin, standards hardly out of bloom; Pears very thin of bloom. Wall fruits: Apricots abundant, more especially on west aspects; Peaches and Nectarines a fair crop; Plums light, Cherries light, Pears also light; Figs where unprotected nearly killed. Black aphides has already made its appearance on the Cherry trees, and also on the Peaches and Nectarines. Gooseberry trees very healthy—no caterpillars, the cuckoo keeping them down altogether. I think the fruit prospects better than they have been for years.

*Apropos* of caterpillars, the crop of a young rook was opened a few days back, and 170 caterpillars were taken from it. Something like three hundred young rooks were shot at one shooting bout. How much more harm was done by the destroyer than by the destroyed! and when will agriculturists learn to value their best friends?—J. GADD.

#### ANNUALS FOR BOUQUETS.

IN many gardens the bedding-out system is, or has been, carried out to such an extent that many things that were familiar enough to the gardeners of twenty years ago have been gradually but surely pressed out of cultivation. With this change in fashion we have now many young practitioners who are but very moderately acquainted with the beautiful and easily cultivated annual flowers that were once so common, and which many employers would be pleased to see again around them. I will not enter into the right or the wrong of the bedding-out fashion, there being room for all systems with us; but to know only one style and to practise no other is certainly not wise.

There are positively "good" gardens, as the phrase goes, where if you were to express a wish to have a bouquet containing no *Pelargoniums*, *Heliotrope*, *Calceolaria*, and *Verbena* the "good gardener" would be puzzled as to how he should oblige you! It is not my design to give any long list of names of annuals—these can be found in any trade circular, but merely to indicate the improvement that might easily be made in this matter. The gardener would not find any appreciable increase in his labours by the cultivation of annuals, and he would be frequently relieved from his embarrassment when many flowers are in request by the lady of the house, and he who has a good quantity of plants in variety all through the season need not be niggardly with these charming simple flowers.

The *Immortelles* are a class of annuals useful in early autumn and onward till frost nips them. They are various in colour, being pure white—as in *Ammobium alatum*—straw-yellow, rose, and white in *Helichrysums*, rose and white in *Rhodanthe Manglesii*. If cut off before the blooms are fully expanded and dried in a box or a loft they are especially useful in "helping out" with a winter bouquet. *Centaurea Cyanus* is a useful bold blue flower, telling well in loosely made table bouquets. *C. moschatus alba* is also good. The varieties of *Gaillardia*, such as *picta*, *Josephus*, *grandiflora albo-marginata*, and *Amblyodon*, are conspicuous either in groups in the borders, and always useful for cutting. *Phlox Haagiana* and *Drummondii* are so good and constant in blooming that they are even useful for the "ground painting," but as a bouquet flower not be despised either mounted or on the natural stalk. As a yellow and orange colour, and with an odour that is agreeable to some people, may be mentioned the small Marigolds—*Tagetes signata*, *T. patula*, and *T. lucida*. These plants are all very fine bloomers, continuing till the arrival of winter. The *Scabiouses*, such as *grandiflora candidissima*, *S. grandiflora flore-pleno*, *S. nana striata*, are all of them very attractive. The *Statice*—*sinuata*, *Thouinii*, both blue, and *Bonduellii*, light yellow—commend themselves on account of their light feathery masses of colour, and by their entire freedom of form—of contrast with the stiff forms we meet with in gardens now-a-days, and of their usefulness in all descriptions of bouquet-making. They flower so abundantly and so long that everybody should

have a patch or two of them. *Statice incana*, *eximea*, *latifolia*, and *coccinea* are perennial species, equally as useful for the purpose indicated.

Balsams may be grown as well or better out of doors than in pots, provided the ground be good and the situation open and warm. The blooms are of great service when mounted, do not wither very soon, and admit, owing to the delicacy and variety of their colours, of many combinations. The *Dianthus* is such an extensive class now-a-days that it may just be necessary to mention a few of the best for the purpose in question. *D. imperialis*, with magnificent double flowers in great variety of colour, and its variety *albus plenus*; *D. Heddwigii* in many sorts, especially *laciniatus* and *laciniatus striatus*. *D. diadematus* is also very fine. With these and the well-known biennials, such as Stocks, Wallflowers in great variety, Sweet Peas, Clarkias, and a host of others, sweet-scented or not but always pretty, the ladies of the family "can cut and come again," and need not fear that by so doing they are destroying the form, or robbing of its buds or wood any choice plant that may have cost the gardener great care to grow to its present state.—F. MOORE.

#### THE USES OF FRAMES IN SUMMER.

THESE being cleared of bedding plants can now be utilised for growing fruits and plants, and the following hints may possibly be of service to some amateurs who are ever thirsting for information.

By maintaining a suitable temperature—that is to say, by avoiding cold draughts of air, and by closing early with moisture, and by giving air more or less according to external temperature, Melons and Cucumbers may be grown to perfection in unheated structures, while Tomatoes will succeed in an ordinary greenhouse temperature.

*Melons and Cucumbers*.—Seeds of these may still be sown singly in 4-inch pots and placed in a gentle hotbed. Keep the young seedlings as near the glass as possible, and before they become much rootbound shift into their fruiting quarters. It will be an advantage, however, if plants are provided or can be obtained ready for planting. They may be fruited in 15-inch or 18-inch pots, tubs, or boxes of near the size of these pots, or on mounds of earth. A rich loamy soil is suitable for both, and in the case of the Melons this should be well rammed down about the roots. Both kinds to be trained on a trellis (easily constructed of wire or strips of wood) about 10 inches or 12 inches from the glass of the roof. Support the plants and rub out side shoots till the trellis is reached in the case of Melons, after which continue to train the leading shoots and tie out the laterals, stopping the former when about a yard up the house and the laterals at the second joint, and these if not already showing fruit will invariably do so at the next break. The Cucumbers may be stopped near the commencement of the trellis, and a few of the top shoots laid in; these will fruit and should be stopped at their second joints, and all succeeding growths to be so stopped and kept tied up where required. Neither kind should be allowed to become dry at the roots. Care must be taken not to give too much water when first planted, and always use water slightly warmer than the temperature of the house. Dell's Hybrid, Victory of Bath, Earl of Beaconsfield, green flesh; and Read's Hybrid, scarlet flesh, and Scarlet Gem, are good varieties of easy culture.

*Tomatoes*.—These may be fruited in various ways. A valuable crop may be taken from single plants in 11-inch pots, or two plants in larger pots. Supposing there are a number of plants already prepared for planting in the open, select some of the best of these, and pot them in rough soil consisting of two parts of loam to one of decomposed manure; pot deeply so as to allow for a liberal top-dressing of soil later on; place in the front of the frame, and train single stems near the glass; rub out all side shoots as they form, and stop the leader beyond the third bunch of bloom. A slight increase of heat will much advance the crop.

*Various Plants*.—By increasing the temperature for any of the foregoing the growth of many other flowering and fine-foliaged plants will be much quickened. Coleuses, Caladiums, Ferns, Begonias, Celosias, Cockscombs, Gloxinias, Achimenes, Torcnias, and other favourites will succeed admirably in frames, and will be useful for house decoration. Plants of any description when received by post should at first be immersed in tepid water, potting them off when thoroughly freshened. As many of the plants so received have but few roots and have been grown in rather a high temperature, place them in very small pots, and if possible in a warm frame, and shade carefully from bright sunshine. When established pinch out the points of those of a

branching habit, such as Fuchsias, Coleuses, and Petunias, and repot them before they become rootbound.—AMATEUR.

#### RAISING VINES FROM EYES VERSUS LAYERS.

IN raising Vines for pot culture to fruit the following season I prefer eyes, about  $1\frac{1}{2}$  inch in length, prepared something similar to a Rose bud with the wood left in. These are placed horizontally just below the surface of the soil in 60-sized pots, using rather fine turfy loam. About the middle of February they are plunged in an ordinary two-light Cucumber frame, after which they are placed in a pit and shifted on, their final shift being in 10-inch pots, where they show fruit at every joint the following season. Of course they are treated liberally and afforded every opportunity to make wood and ripen the same thoroughly; and when

the forcing time comes round they are placed on the front stage (stone slab over the pipes) of an early vinery started this year on the 20th of January, the pot Vines being eleven months old at that time. They are top-dressed with cow manure, and the soil in the pots well intermixed with bone meal, in my opinion the very best manure for the purpose yet obtainable. Six nut wands are placed at equal distances around each pot inside, and the Vines coiled around the sticks in the bottle-screw style: the sticks are not much over 2 feet above the rim of the pots.

The variety we find to be the surest cropper is the Black Hamburgh. We have had from ten to thirteen bunches on these Vines. Six of those Vines were exhibited at the Maidstone Horticultural Society's Show the last August, and received a special award. If "A KITCHEN GARDENER'S" layering practice would be the slightest improvement on the above I would be pleased to adopt

Fig. 105.—LAVATERA ARBOREA VARIEGATA—NATURAL-SIZED LEAF.

it, but I am very dubious. However, we will see what other growers may have to say on the eye system of raising Vines *versus* layers.—W. H. C., Tunbridge.

#### LAVATERA ARBOREA VARIEGATA.

VERY rarely indeed does it fall to our lot to figure for the first time and introduce to our readers a new border plant so striking in appearance as the variegated Tree Mallow which we now submit. When Mr. Smith, The Gardens, Clevedon Hall, Somerset, first sent us leaves of his new acquisition we were almost startled by their markings, and on subsequently receiving flowering sprays of the plant we were still more convinced of its distinctness and beauty. The history of the plant is brief, and may be told by its discoverer, who writes—

"I found a plant 6 inches high growing in a neglected cottage garden. I made an exchange for a few bedding plants, and was very

pleased with my bargain. I have propagated several plants, and I have not yet seen one but what is beautifully variegated. It is a fine shrubby border plant, growing 6 or 7 feet high, and I find the leaves very useful for garnishing late Grapes when Vine leaves are not to be had. I believe the variegated Lavatera to be as hardy as the green species, which lives only through mild winters in this neighbourhood. The last two or three winters have been too severe for it. I kept my plants last winter in an unheated Peach house. I may mention that the entire stock is in my hands."

The figure on the next page is a truthful representation of one of the sprays sent to us, reduced in size, and the others were equally good. We have had a natural-sized leaf engraved separately, the artist having had instructions to show its markings with great exactitude. The irregular mixture of very dark green, pale greenish grey, and pure white impart to the plant a remarkable appearance. The plant appears to us to occupy a position amongst border plants similar to that of the Variegated Maple in shrubberies.

We may add, that although the variegation is so pronounced and the white so pure, there is not the slightest indication of weakness in the sprays, but, on the contrary, they are as strong

and vigorous as green specimens. We have described this as a new plant because it is new to us, and if anyone else should happen to have been equally fortunate with Mr. Smith in obtain-

Fig. 106.—*LAVATERA ARBOREA VARIEGATA* (SMITH), REDUCED FIGURE.

ing and perpetuating this variety so much the sooner will it have a place in the gardens of this country.

**PAINTING VINES—A MISTAKE.**—That mistakes eventually lead

to success and perform a material part in the making-up of a practical gardener I believe, but perhaps it is equally true that few care to admit of error. Excuses are more fashionable. It is my usual practice to fruit what Vines I have that remain unsold, and this year I had left a fine batch of Alnwick Seedling. Having

some of that valuable mixture for Peach trees—Scotch snuff, sulphur vivum, and quicklime in equal parts, with it I painted some of the young canes, planted them, and shortly after commenced syringing. This washed the mixture down to the roots, and instead of the Vines growing they died, and on pulling them up the roots were all black and dead. The same fate undoubtedly has followed the application of other mixtures when reasonable precaution has not been taken.—JOSEPH WITHERSPOON.

#### WHAT PLANTS USE.

POSSIBLY much of what appears in the following remarks may have appeared again and again in the Journal, but much of it needs reiteration in order to its being pressed home on the minds of those to whom it is addressed. Horticultural writers, who quite understand what they are writing about, often fail to convey their meaning to those they address; and if they should accomplish this much, still, little useful purpose is served, for unless readers understand the reason why certain courses should be followed it is seldom that they are followed. Thus it is no uncommon thing for novices in Grape culture, after reading that "Vines require abundant supplies of water," to forthwith thoroughly wet the surface of their Vine borders and nothing more, and be eminently satisfied with their work, while all the while the Vines are languishing for want of water. It is commonly understood that vineries need to be ventilated, but the why and the wherefore few seem to understand. We do not refer to novices only, for we are convinced "air-giving" is not so well an understood matter by even many good gardeners as it ought to be. It is not seldom that men have gained laurels and made names for themselves by merely imitating the successful practice of others. Were there fewer mere imitators and more practitioners who acted understandingly, we should not read and hear such sentences as these,—"Where Mr. So-and-so succeeds others might fail"—so often. Men fail because they do their best to imitate only. Were they to do nothing without understanding it, systems practised with the greatest success by some would not become so often discredited by others failing to do likewise. Certainly our practice ought to be judged by the success or otherwise which attends it; but there can be no doubt that the man who understands is more likely to succeed than the mere imitator. The one walks in light and can see the rocks ahead and avoid them; the other gropes in darkness, and suffers shipwreck or escapes by a miracle. To be able to steer a safe course some knowledge and much study are required. Indeed, every gardener would require to be somewhat of a philosopher. We lay no claim to that title. We have dabbled in science, and tried to make science helpful in our practice, and have imagined, at least, that it has been so; and now beg to offer a few crude observations in the hope that at least the less informed among your readers may be thereby benefited.

We have headed our remarks "What Plants Use," and have incidentally mentioned vineries; we will, therefore, make the following remarks apply as much to Vines as possible, although much of it may be applied to any other plant cultivated under glass.

Vines use air, light, heat, water, and a number of mineral matters. We will in this paper confine our remarks to air, light, and heat. It may seem a wonderful statement to some to say that after water air yields to Vines the greater part of their substance. The Vines themselves are chiefly formed from the carbonic dioxide which is present in the atmosphere to the extent of 1 in 2500 only, and yet the leaves, the fruit, the stems, and even the very roots which burrow in the earth, derive nearly all their substance from water—pure water, and the very small amount of carbon which is everywhere present in air in the form of carbon dioxide gas. The roots take in the water, the leaves inhale the gas, and cause the water and gas to be converted into something quite different from either. Water is a compound consisting of hydrogen and oxygen, and carbon dioxide is a compound of carbon, familiar to us as charcoal, coke, soot, &c., and oxygen. By a wonderful process not quite understood the plant causes these substances to cease being water and carbon dioxide gas, and reconverts them into wood, starch, gum, sugar, and a great many other substances called carbo-hydrates (hydro-carbons), because they are formed from the elements of water (hydrogen and oxygen) and carbon. All our vast coalfields, our bogs—at least the peat that is in them—the mighty forests that supply our timber; the cornfields that supply our bread, our sugars, oils, teas, coffees, spices, our clothes; almost everything we possess, which is not stone or metal, has been formed of water and the carbonic dioxide which is present in the atmosphere in the small proportion we have named.

Small as it is, it is amply sufficient, however, if a current of air be constantly passed over the leaves. In nature this is constantly occurring, but not always in vineries. The leaves of plants, and especially deciduous trees, are densely studded with open greedy mouths—stomata they are called—which inhale the air and rapidly extract the carbon from the carbon dioxide, and set the oxygen free. "On a single square inch of the common Lilac as many as 120,000 have been counted, and the rapidity with which they act is so great that a thin current of air passing over the leaves of an actively growing plant is almost immediately deprived by them of the carbonic acid it contains—(*Chemistry of Common Life*, page 58, new edition). What is true of the Lilac is no less true of the Vine; and as a matter of fact Vines, even under diffused sunlight, when in a temperature of over 60° deprive the air of its carbon as rapidly as it is admitted by ordinary ventilation, and when no ventilation at all is given the air very soon becomes quite exhausted, and the Vines fail to find what is absolutely necessary to their well-being.

In the absence of light—that is, during darkness, plants cease to manufacture the raw materials—air and water, into tissue-forming matter. Nay, when growing temperatures are maintained during darkness these operations are reversed, and much of the work done by day is undone by night. Vines in a temperature of 60° and upwards are always doing something. By day they build their structures; by night they, to an appreciable extent, unbuild it. On the other hand, when the temperature falls below 50° they do next to nothing at all—they rest.

We have seen that under a high temperature, strong sunshine, and a plentiful supply of air and other necessary matters, plants grow with rapidity. It requires no science to teach us that—we are familiar with the fact; but we are far too apt to ascribe the whole to the high temperature only. It is not so, however. Light is as necessary as heat, and heat of itself is not enough; it may, indeed, do more mischief than good. Under a dull sky leaves do not perform their functions so rapidly as under bright sunshine, even though the temperature should be artificially kept high. The exclusion of air, then, in order to maintain, say, a temperature of 80° is not good practice, and certainly tends to cause weakness in time. It is better by far to maintain a current of air in order to maintain a proper supply of carbon, even although by so doing the temperature should not be over 70°; indeed, we doubt if Vines will decompose carbonic dioxide and water more rapidly in a temperature of 80°, when the light is weak, than they will in one of 70°. With unobstructed sunrays acting on the leaves the case may be different, but there can be no doubt that the right thing is to make the heat and air supplies correspond with the light. We are quite aware that high temperatures induce precocity, and that forcing is a race against time with many; but hard forcing accompanied with closed ventilators means speedy ruin. It is not so much the unnatural season at which early Vines and Peaches are forced which causes their early decay as the unnatural way they are forced. It is quite true that we often cannot help ourselves—that is a phase of the subject we cannot enter into here—but the fact nevertheless remains that forwarding the Vines by night and cheating them of a full supply of air by day is ruinous.—SINGLE-HANDED.

(To be continued.)

#### MANCHESTER ROYAL BOTANIC

AND HORTICULTURAL SOCIETY.—JUNE 3RD TO 10TH.

THE above Society has again held a grand display of plants. In few places can a society boast of some 50,000 spectators visiting their exhibition, as was the case last year, and no doubt it will be as much thronged this as in previous years. The long line of carriages and the vast stream of ladies and gentlemen that poured in as soon as the Exhibition was opened gave a good idea of the popularity of the Society and the success that evidently attends its shows. One of the chief features of the event was the large number of Orchids, which were admitted to be the best ever seen in the Botanic Gardens. The first-prize collection staged by R. B. Dodgson, Esq., Blackburn, will long be remembered. The Orchids were arranged along the front on either side of the large Exhibition house, with the collections of stove and greenhouse plants in the background. The long table down the centre contained the miscellaneous collections of plants from Messrs. B. S. Williams, London, and R. P. Kerr & Sons, Liverpool. To the right were staged the large plants of Messrs. Cypher and Sons, Cheltenham, and on the left those of Messrs. Cole & Sons, Withington. At the further end of the house were arranged the amateurs' collections, and J. F. Williams, Esq., Worcester, well deserved the honours awarded him. It is questionable if he ever staged plants in better form and condition. Passing into the next large tent, hitherto so famous for the noble specimen Roses shown in previous years; although the Roses were missed, the tent contained a choice collection of hybrid Rhododendrons from Messrs.

John Waterer & Sons, Bagshot. They were all planted out in the beds occupied with plants during previous exhibitions. They were not quite at their best, but the display was gorgeous and the change all that could be desired. On the right hand side of entering were the Clematises exhibited by Messrs. R. Smith & Sons, Worcester, and the collection of Maples, both being highly creditable to the firm. The third tent was much larger than usual, and was, on the whole, brighter than in previous years. It contained many of the dwarf-growing Ferns, both hardy and exotic, also the Ericas, Zonal Pelargoniums, and a collection of plants from Messrs. J. Standish & Co. the front of the stage being edged with Strawberries in pots and Pansies. The stage, which occupied the centre, was three parts filled with herbaceous and Alpine plants. These were far more numerous than at any previous show, and attracted much attention.

**Stove and Greenhouse Plants.**—In the class for twenty plants, ten in flower and ten fine-foliage, there were only two exhibitors—Messrs. J. Cypher, Cheltenham, and Messrs. Cole & Sons, Withington, taking the prizes in the order named. In the first-prize collection were *Latania borbonica*, *Areca lutescens*, *Thrinax elegans*, *Encephalartos villosus*, *Verschaffeltia splendida*, all large and in good condition; *Croton Wiesmanni* and *C. Disraeli* were well coloured; *Clerodendron Balfourianum* and *Bougainvillea glabra*, well flowered, 5 feet through; *Azaleas elegantissima*, *Holfordianum*, and *Le Conquerante* were each 5 or 6 feet in diameter at the base, and well flowered; *Pimelea spectabilis rosea*, *Dracophyllum gracile*, and *Gleichenia speluncæ* were also fine. Messrs. Cole & Son had fine examples of *Cycas revoluta*, *Latania borbonica*, *Kentia Forsteriana*, *Erica Cavendishiana*, and *E. ventricosa magnifica*, both the latter flowering well. The *Azaleas* were the chief feature in this collection, and large well-flowered plants of the following were staged—*A. Criterion*, *A. Iveryana*, *A. Mrs. Fry*, and *A. Magnificent*. In the corresponding amateurs' class there were five competitors, Mr. Tudgey, gardener to J. F. Williams, Esq., Worcester, being a good first. The best plants were *Pritchardia pacifica*, *Cycas circinalis*, *Latania borbonica*, *Geonoma gracilis*, *Cycas revoluta*, 7 feet through; *Cocos Weddelliana*; *Croton Johannis*, well coloured; *C. Queen Victoria*, very fine, about 4 feet through; *Ixora Williamsi*, well bloomed; *Erica Cavendishii*, *E. ventricosa magnifica*, *E. ventricosa coccinea minor*, all large, well, and densely flowered. The second prize was secured by H. Samson, Esq., Bowden, who staged fine specimens of *Gleichenia rupestris* and *G. flabellata*, *Cycas revoluta*, *Ixora Colei*, *Statice profusa*, and a handsome *Anthurium Schertzerianum*. Third Mr. C. Paul, gardener to S. Schloss, Esq., Bowden, with *Stephanotis floribunda* on a trellis 5 feet high; *Anthurium Schertzerianum*, very fine; *Azalea Napoleon III.*, *Acrophyllum venosum*, and *Genetyllis tulipifera*, all healthy. In the class for eight stove and greenhouse plants John Rylands, Esq., Stretford, was placed first with rather small but neat plants; Mr. Samson, Bowden, being a good second.

**Azaleas.**—In the open class for six greenhouse *Azaleas* Messrs. Cole and Sons were the only exhibitors, and staged very creditable plants of *A. Duchesse Adelaide de Nassau* and of *A. Trotteriana* among others. In the corresponding amateurs' class G. Hardy, Esq., Timperley, was the only exhibitor, and staged a very fair collection, including a healthy well-flowered example of the beautiful bright orange variety *Marquis of Lorne*.

**Ericas.**—These were more largely shown than on some previous occasions, and the plants were both good and well flowered. Messrs. Cole & Sons were first with good plants of *E. ventricosa*, *E. tricolor major*, *E. Cavendishiana*, *E. Victoria regina*, *E. ventricosa coccinea minor*, and *E. Lindleyana*. Messrs. Cypher & Sons were second with slightly smaller plants. Mr. Williams, Worcester, obtained the first award for vigorous plants in the amateurs' class for six, Mr. H. Samson being second with smaller plants, but neat and healthy.

**Crotons.**—In the open class for eight *Crotons* Messrs. R. P. Kerr and Sons, Liverpool, obtained the premier award, showing good well-coloured plants of *C. Johannis*, *Prince of Wales*, *Morti*, *Hawkeri*, *Hanburyanus*, *Evansianus*, and a remarkably fine plant of *Croton interruptus aureus*, well coloured. Messrs. Cole & Sons were second with much smaller plants of *Prince of Wales* and *C. Disraeli*. In the class for six varieties R. B. Dodgson was first, the best plants being *Queen Victoria*, *Earl of Derby* (very good), and *Prince of Wales*. Mr. Schloss was second, having a good plant of *Wiesmanni* and other kinds, such as mentioned above; Mr. John Rylands taking the remaining prize.

**Dracenas.**—In the open class for ten plants Mr. B. S. Williams, Upper Holloway, was the only exhibitor, and was awarded the first prize for good plants of *D. Robinsoniana*, well coloured; *D. Thomsonii*, a very fine variety much after *D. Renardiae*; *Albo-marginata*, very fine; *D. Caustonii*, *D. Mrs. Freake*, *D. majestica*, *D. Wilsoni*, and the beautiful narrow-leaved *D. superba*. In the class for six plants Mr. R. B. Dodgson was the only exhibitor, and staged good plants of *D. Youngi*, *D. Chelsoni*, *D. Baptistii*, *D. Mooreana*, *D. amabilis*, and *D. excelsior*, and was awarded a first prize.

**Orchids.**—As before stated these were numerous and good. The display was highly effective and an interesting exhibition in themselves. In the open class for sixteen exotic kinds Mr. B. S. Williams, as usual, obtained the highest honours in the nurserymen's class, which the collection well deserved. It included *Cypripedium Stonei*, with its large and curious flowers; *Lælia purpurata Brysiana*, a fine variety with eight large flowers; *Epidendrum vitellinum majus*, with about forty of its rich orange scarlet spikes; *Calanthe vejatifolia*

with ten spikes; *Dendrobium crystallinum*; *Vanda tricolor insignis*, a fine plant; *Cattleya Mossiæ superba*, with eight flowers and several unexpanded; *Masdevallia Veitchiana*, well flowered; *Calanthe Dominiana*, with eight spikes; *Cypripedium barbatum superbum*, with from thirty to forty flowers; *Cattleya Mossiæ*, with seventeen flowers; *Lælia purpurata*, ten flowers; *Masdevallia Lindeni*, good; *Odontoglossum vexillarium roseum*, very large flowers, bearing three spikes; *O. cordatum* having nine spikes. Messrs. J. Cypher & Sons were second with much smaller and weaker plants. In the corresponding amateurs' class Mr. R. B. Dodgson was first with excellent plants of *Masdevallia Harryana*, with about forty spikes; *Dendrobium Ainsworthii*, a well-flowered plant; *Odontoglossum vexillarium*, fully 2 feet 6 inches in diameter, with over thirty spikes; *Cypripedium villosum*, 3 feet in diameter, covered with flowers; *Lælia purpurata*, a fine variety with eighteen flowers; *Masdevallia Veitchiana*, with about fifty flowers; *Dendrobium thyrsoiflorum*, with sixteen extra large spikes; *Cypripedium biflorum*, fully 3 feet over, and well flowered; *Cattleya Warneri*, grand, with twenty-six flowers; *Vanda suavis*, twelve spikes; *Epidendrum vitellinum majus*, with about thirty spikes; *Cypripedium barbatum superbum*, 3 feet through and covered with flowers; *Cattleya Mossiæ*, twenty-one flowers; *Masdevallia Harryana splendens*, a very fine variety; and *Dendrobium Wardianum*, well flowered, with stems nearly 4 feet long. The second collection, from Mr. J. Hill, gardener to G. Hardy, Esq., Timperley, was also very good, especially the *Cattleyas*, his best plants being *Cattleya Mendelli*, with eighteen flowers; *C. Mossiæ grandiflora*, with thirty-three flowers; *C. Mossiæ aurea*, very fine, twenty-nine flowers; *Odontoglossum vexillarium*, with twenty-three spikes; *Vanda Denisoniana*, *Dendrobium thyrsoiflorum*, var. *Walkerianum*, with twelve very large spikes; a well-flowered *Dendrobium Bensoniæ*; and the fine *Oncidium Marshalli*, the latter well representing the packing system, two varieties being together in the same pot.

In the open class for ten Orchids Mr. B. S. Williams was again first with a fine collection, and Mr. J. Cypher second with very small plants. In the amateurs' class for nine Mr. E. Mitchell, gardener to Dr. Ainsworth, Higher Broughton, was first with *Phalaenopsis grandiflora*, eight or nine plants packed together in a large pot bearing about ten good spikes, *Saccolabium præmorsum*, a grand variety, with six large spikes, *Dendrobium Jamesianum*, *Dendrobium crassinode* with stems fully 3 feet long and well flowered, *Vanda tricolor*, *Aerides Fieldingii* seven spikes, some of which were fully 18 inches long, and a good plant of *Odontoglossum vexillarium*, but the flowers rather short of colour. Mr. Dodgson was second with neat plants of *Cypripedium Stonei*, *Cattleya Mendelli*, *Odontoglossum vexillarium*, *O. citrosum*, and *Dendrobium Schröderi*. In the class for six Mr. G. Hardy took the lead. The second prize was secured by Mr. W. Sherwin, gardener to W. Sparks, Esq., Huyton, Liverpool, who showed fresh and neat plants, but not quite so large as the preceding. For three Orchids Mr. Hardy was again first with *Dendrobium thyrsoiflorum* with nine spikes, *Odontoglossum vexillarium* thirteen spikes, and *Cattleya Mossiæ marmorata* with thirteen flowers. Second, Mr. J. Aitken, gardener to J. H. Allan, Esq., Timperley, with *Brassia verrucosa*, *Cattleya Mossiæ superba*, and *Odontoglossum Pescatorei*. In the class for one Orchid Dr. Ainsworth was first with *Phalaenopsis grandiflora*, Mr. Tudgey second, and Mr. J. Aitken third. In the special prize class for six specimens (single plants), the first and second prizes given by Henry Shaw, Esq., Buxton, Dr. Ainsworth was first with *Saccolabium præmorsum* with two spikes, *Aerides Schröderi* six spikes, *Vanda suavis*, *Cypripedium villosum*, *Aerides Fieldingii*, and *Phalaenopsis grandiflora*. Second, Mr. D. Broadman, gardener to G. Hodgkinson, Esq., Dunham Massey, with *Vanda suavis*, *Dendrobium nobile*, *Cattleya Mossiæ*, *Lælia purpurata*, *Brassia verrucosa*, and a fine basket of the lovely *Dendrobium Faleoneri*.

**Ferns.**—These were not shown in large numbers, but the plants staged were in the best possible condition. In the class for eight stove and greenhouse Ferns Mr. S. Schloss staged a fine collection, and the *Gleichenias* were really well grown, being from 6 to 7 feet through. The following were most noteworthy:—*Gleichenia flabellata*, *G. Mendelli*, *G. dichotoma*, *Goniophlebium subauriculatum*, *Davallia Mooreana*, and *Davallia tenuifolia*. Mr. J. Hesketh, gardener to A. Birley, Esq., Pendlebury, was second, having large plants of *Cyathea medullaris* and *Cibotium Schiedei*. Third Mr. Tudgey, a fine plant of *Microlepia hirta cristata* being notable. In the class for six *Adiantums* Messrs. R. B. Dodgson, George Hardy, D. Broadman, and D. Adamson, Didsbury, obtained the prizes in the order named, the latter two being equal. In the first collection the Ferns best represented were *Adiantum euneatum*, *A. tenerum*, *A. formosum*, *A. concinnum latum*, and *A. excisum*. Hardy Ferns were rather numerous, the plants being robust. The first prize in the class for twelve was obtained by Mr. Charles Ryland, Aughton, Ormskirk, the following being his best plants:—*Athyrium Filix-femina Fieldiæ*, *A. F.-f. Cragi*, *A. F.-f. Friselliæ*, *A. F.-f. plumosum*, *A. F.-f. grandiceps*, *A. F.-f. Elworthæ*, *Lastrea Filix-mas grandiceps*, *L. F.-m. cristata*, *L. F.-m. angustata*, *Polystichum proliferum*, *P. angulare cristatum*. An extra prize was awarded to Mr. F. W. H. Stansfield, Todmorden. In the corresponding amateurs' class the prizetakers were Mr. Brookbank; Mr. John Leech, gardener to John Wild, Esq., Stand; and Mr. A. Birley in the order named, showing similar varieties to those above enumerated. In the class for six Filmy Ferns Mr. Tudgey was first with good plants of *Trichomanes radicans*, *Hymenophyllum*

nitens, Todea superba, Hymenophyllum demissum, and H. tunbridgense. Mr. J. Rylance was second, and Mr. G. Smith third.

*Roses*.—These were very poorly represented, and those shown need but a passing notice. In the class for twenty plants in 9-inch pots there was only one exhibitor—namely, Mr. H. May, Bedale, some of his plants bearing a dozen blooms. In the class for six plants there were two exhibitors, Mr. R. Elphinstone, gardener to John Heywood, Esq., Stretford, taking the lead with fair plants but rather past their best and the flowers small. The second prize was awarded to Mr. W. Brockbank.

*Palms and Yuccas*.—In the class for four Palms there were three exhibitors. Mr. G. Hardy, Mr. Upjohn, gardener to Lord Howard, Glossop, and Mr. John Rylance secured the prizes in the order named. The first collection included clean and well-grown plants of *Geonoma princeps*, *G. gracilis*, *Latania borbonica*, and *Cocos Weddelliana*. In the class for two Yuccas, Mr. D. Adamson, Mr. S. Schloss, and Mr. G. J. Morton, gardener to James Fildes, Esq., were the prizetakers.

*Pelargoniums*.—These plants produced a very brilliant effect and were shown in excellent condition, and the competition was keen in some instances. In the class for eight Show Pelargoniums Messrs. Lazenby & Sons, York, exhibited some handsome plants and gained the first prize. The specimens were not quite so flat as those generally shown, and looked much better on that account. They were densely covered with flowers, and it would be a difficult matter to produce better plants. The varieties were Hermit, Duchess of Edinburgh, Amazon, Queen Bess, Triomphe de St. Mande, Kingston Beauty, and Digby Grand. Mr. Charles Rylance was second with smaller and flatter plants but very good, his best being Rob Roy, Albina, Brigantine, Beacon, and Royal Bride. Third, Mr. H. May, Bedale, with good plants of Belle Blanche and Regalia. In the class for eight Fancy Pelargoniums Mr. Robert Gore, Huyton, Liverpool, was the only exhibitor. In the class for twelve Zonal Pelargoniums Mr. C. Rylance was first with good plants, but too many scarlets, the best being Mrs. Whitley, Wellington, Acme, Queen of Beauties, Captain Holden, and Mrs. Jacoby. Messrs. J. Lazenby & Sons were second, having good plants of Lady Emily and Mrs. Hetley. Third, Mr. Robert Gore.

*Pansies*.—These looked well and gay, and made a capital edging for the tables. In the class for twenty in 8-inch pots Mr. Henry Hooper, Bath, was the only exhibitor, and was awarded the first prize for good plants. In the class for twenty Fancies Mr. Samuel Robinson, Sale, was first with a satisfactory collection and very neatly set up. Mr. Henry Hooper was second. The same exhibitors taking the prizes in the order named for twenty Violas; Messrs. W. Joynson, Brockbank, A. Lumbers, J. G. Adams, and D. McClure being the principal prizetakers in the remaining classes.

*Clematis*.—In the class for fifteen specimens Messrs. R. Smith and Co., Worcester, were the only exhibitors, and staged very creditable well-flowered plants. The best were Marie Lefebvre, William Bennett, Henryi, Victoria, a fine variety; Gloire de St. Julien, Lord Nevill, Hybrid Perfection, and Excelsior. In the class for six kinds Mr. Elphinstone won with good well-flowered plants of *Lanuginosa candida*, Lord Nevill, Sensation, Marie Lefebvre, and Empress Eugénie.

*Alpine and Herbaceous Plants*.—These were, as before stated, shown in large numbers and in fine condition. They were the chief feature of the tent in which they were staged, and gave an excellent opportunity for admirers of this class of plants to make selections. Those staged in the open class by Messrs. J. Dickson & Sons, Newton Nursery, Chester, were very fine; eighty specimens were staged, and all in good condition. A few of the most striking were *Spiraea palmata*, *Delphinium Madame Pélé*, *Hesperis matronalis flore-pleno*, *Iberis corifolia*, *Spiraea Filipendula flore-pleno*, *Saxifraga Cotyledon* with a pyramidal spike of light flowers 3 feet in length; *Scilla peruviana*, *Lychnis lagascea*, *Vriesia coccinea*, *Erinus alpinus*, *Lupinus polyphyllus*, *Dietamnus Fraxinella*, *Pyrethrums*, *Geums*, and others. The second prize was awarded to Mrs. Brownhill, Sale, Manchester, a few of the best plants being *Caltha palustris flore-pleno*, *Saxifraga intermedia*, *Saxifraga Wallaei*, *Czakia liliastrium*, *Pyrethrum Progress*, *Saxifraga pyrenaica*, and *Ranunculus aconitifolius flore-pleno*. For thirty-six Mr. W. Brockbank was first with an excellent assortment. Mr. Wm. Plant, gardener to R. P. Gill, Esq., Ashton-on-Mersey, and Mr. J. Kay, Prestwich, second and third. In the first group were *Geranium ibericum*, *Papaver pyrenaicum sulphureum*, *Lamium longiflorum*, *Primula farinosa*, *Phlox Nelsonii*, and *Aquilegia juncunda*.

*Nepenthes and Sarracenias*.—For the best collection Mr. B. S. Williams was the only exhibitor, and staged a few very interesting species, such as *Nepenthes intermedia*, *N. robusta Kennedyana*, *N. hybrida maculata*, *N. rubra*, *N. Stewarti*, *N. Hookeriana*, *N. Rafflesiana*, *N. Dormaniana*, *N. ampullacea*, *Sarracenia purpurea*, *S. major*, *S. variolaris*, *S. flava maxima*, *S. Drummondii*, and the curious little *Drosera spatulata*.

*New and Rare Plants*.—In this class for twelve plants Mr. B. S. Williams and Mr. J. Cypher were the only two competitors, the former taking the lead, and showing *Dracena Earl of Derby* very fine, *Philodendron elegans*, *Adiantum Williamsi*, a good plant; *Thrinax gracillima*, *Croton Warreni*, *Anthurium Waroequeanum*, *Oleobachia palustris*, *Dracena Goldiana*, *D. superba*, *Cyphokentia robusta*, *Dieffenbachia Imperator*, and *Lastrea membranifolia*. Mr. J. Cypher showed *Anthurium Schertzerianum densifolia*, *Croton*

*interruptus aureus*, *Sabal cœrulescens*, *Microlepis hirta cristata*, *Croton Mortii*, *Cymbidium Lowianum*, *Croton Wilsoni*, and *Anthurium Schertzerianum Hendersonii*, a fine large spathe. In the class for six Mr. Dodgson was first with *Nepenthes Lawrenciana*, *Oleobachia palustris*, *Alocasia Thibautiana*, *Cryptopodium Lawrenciana*, and *Philodendron elegans*; Mr. Tudgey being second with *Anthurium Andreanum*, *Gleichenia dicarpa longipinnata*, *Croton Hanburyanus*, *Croton Warreni*, and *Ixora Duchess of Teck*.

*Fruit*.—For a collection of ten dishes Mr. Wm. Pratt, gardener to Lord Hill, Hawkstone, was the only exhibitor, and staged a very creditable collection considering the season. The collection contained two bunches of Black Hamburgh Grapes, two Pines, Grosse Mignonne and Early Rivers Peaches, President Strawberries, Brown Turkey and Grosse Monstrueuse de Lipari Figs, Hawkstone Seedling and Eastnor Castle Melons. Mr. A. Jameson, gardener to the Earl of Crawford and Balcarres, was first in the class for two bunches of Black Hamburgh Grapes with good examples; second, Mrs. Ackers, Congleton; and third, Mr. J. Hand, gardener to J. Knowles, Esq., Bolton. For two bunches of white Grapes Mr. W. Breese, gardener to Mrs. Ackers, was first with Duke of Buccleuch, fine large berries, but not ripe. For two Pine Apples Mr. McGaw, gardener to F. J. Sumner, Esq., Hayfield, was first; Mr. Faulkner, Wootton Hall, Liverpool, second; and Mr. W. Breese third. Messrs. Faulkner and F. J. Sumner were the exhibitors in the class for one Pine Apple, and secured the prizes in that order. For twelve pots of Strawberries Mr. Faulkner was first with a fine collection of President; second, J. Legh, Esq., M.P., Lyme Park; and third, Mr. McGaw; and Messrs. Dickson, Brown, & Tait exhibited their new Melon Best of All, grown by Mr. McIndoe.

*Miscellaneous Exhibits*.—A beautiful collection of choice stove and greenhouse plants was exhibited by Mr. B. S. Williams, not for competition. The plants were all small, and included the newest *Dracenas*, *Crotons* of which one called *Rodeckianus* promises to be a useful kind. A pan of *Cyperus laxus variegatus* was also in the group, and is a decided improvement upon the old *Cyperus*. Palms, Ferns, and others intermixed with small flowering Orchids gave to the group a gay and effective appearance. A similar group was staged by Messrs. R. P. Kerr & Sons; *Croton Dormanianus* was conspicuous, also pans of *Hydrangea stellata*, *Erica perspicua*, and *E. perspicua nana* were freely employed in the group. Messrs. J. Standish & Co., Ascot, exhibited a group of similar plants, with plants of the Tea Rose *Niphetos*, also two large boxes of cut blooms of the same variety, and one box of *Gardenia* blooms.

Messrs. Kelway & Sons, Langport, exhibited a grand display of cut blooms of *Pyrethrums*, a few of the best seedlings being Captain Boyton, Placida, Queen Hilda, Rembrandt, Duchess of Edinburgh, and Captain Dares. Mr. Thomas Ware, Hale Farm Nurseries, also staged a collection of *Pyrethrums*.

This report would be incomplete without taking the opportunity of congratulating the members of the Council upon the success of the Exhibition, and also Mr. Bruce Findley for his indefatigable exertions to carry out the arrangements of the Society in a business-like and successful manner.

### ODD CORNERS.

SOME interesting notes under the headings of "Odds and Ends" have lately been published in the Journal, and I think something might now be said with advantage about "odd corners," which are to be found in all gardens no matter what their size may be. In some cases the cultivators are particular to make the most they can of these, but in the majority of instances they are neglected and add nothing to the supply. There are certain small crops we set apart for growing in odd corners altogether, and I never think of making provision for them in the main quarters. This plan I find economical in every way, and well worthy of being generally followed.

Narrow borders between walks and walls in kitchen gardens are mostly well cropped, but there is often an odd strip close to the bottom of the wall which is left vacant, and this is one of the most valuable parts in a garden for very early and very late crops. There early Potatoes do remarkably well, and amongst them Lettuces and Radishes come in ready for use some weeks before those in the more open quarters. In summer Tomatoes do excellently planted there, and during winter Lettuces, Endive, Radishes, &c., may again be had from the same position with very little trouble. Where much space of the kind exists early Cauliflowers, Carrots, Turnips, &c., may all be secured there, and Dwarf Kidney Beans may also be added to the list of crops suitable for such positions. Parsley, too, is well protected at the foot of a wall during winter, and it may often be gathered there in severe weather when that in more exposed parts has disappeared.

As Vegetable Marrows may now be planted out, odd corners will be found to suit them as well as any other place. The top of any old dung or refuse heap is a capital spot for them provided it is not too much shaded. Spinach and other quick-growing crops may as a rule be grown in odd corners, and young plantations of Broccoli, Savoys, &c., being raised from seed may all

be grown where it would not be thought worth while to sow or plant anything else. Experienced people who see the kitchen garden here generally remark the economical way the odd corners are utilised; but the practice need not be confined to the vegetable quarters. In the pleasure grounds there are often many vacant spots which might be filled with annual and herbaceous plants which would yield a supply of useful flowers in their season, and that too without interfering with other arrangements.

Under glass there are numerous odd corners which may be most profitably employed to produce various useful and ornamental plants. In moderately cool houses Tea Roses may be placed in any spare corner, and numbers of flowers will be had

from them. Tomatoes are also suitable for such places, and a crop may be had from them in a short time, when they may be cleared away to give place to other things. Briefly, anyone who makes the utmost use of all their odd corners for a few months as a trial will never give up the system.—M. M.

#### ADIANTUM BAUSEL.

WE have been asked for particulars relative to this Fern. Our reply is, that it is one of the most distinct and elegant forms of the numerous and deservedly popular Maidenhair Ferns, the peculiarity of which has during the past year attracted much attention. It is reported to be a hybrid between *A. trapeziforme*

Fig. 107.—ADIANTUM BAUSEL.

and *A. coneinum*, obtained at the Anerley Nursery of the General Horticultural Company. Spores of the two species named were sown in one pot, and, among many young plants produced of both forms, one very distinct in character of a drooping habit was observed. This was carefully preserved, grew rapidly, and, proving fertile, spores were readily obtained, from which a large stock of Ferns was raised, possessing all the characters of the parent. But a remarkable origin and peculiarity of form are not the only recommendations of this Fern, for it deserves to rank among the best plants for decorative purposes, and the fronds appear to possess sufficient firmness of texture to endure exposure either in a moderately low temperature or the dry atmosphere of rooms. Certificates have been awarded for it at the chief metro-

politan exhibitions. For the accompanying woodcut we are indebted to the above-named firm.

#### BATH AND WEST OF ENGLAND SOCIETY'S SHOW. TUNBRIDGE WELLS.—JUNE 6TH TO 10TH.

UNDER the skilful guidance of the Hon. and Rev. J. T. Boscawen the horticultural department admirably sustains and adds to its reputation at this meeting, which opened on Monday and closes on Friday. The large tent devoted to flowers is well filled with a host of magnificent specimens, so well grown as to be worthy of close inspection individually, and all of them contributing much to the general effect. There can be no doubt that most of the plants impress the visitors all the more strongly from the consummate taste

shown in the grouping; and the eye wanders delightfully along, pausing to dwell with a keen sense of luxurious enjoyment upon group after group, being attracted by the delightful colour combinations, and then if possible still more enjoyably taking in the grand whole.

All along the centre runs a mass of elegant foliage—Tree Ferns, Palms, Cordylines, and Screw Pines, mingled with huge highly coloured specimens of pyramidal Crotons, Oranges, and Dracenas, lightness and grace predominating throughout, for there is not the slightest approach to heaviness or formality in any part of the arrangements—just a flash of brightness to greet one at the entry, and by way of a parting salutation as we leave, in a narrow bank of Rhododendrons; then the Ferns and Palms, with a charming fringe of colour running all along the front of one side and deepening at intervals into brilliant groups of Orchids, Gloxinias, and stove plants of more pretentious proportions. But along the other side of this grand central grouping there is an agreeable contrast in a margin of the charming greenery of a collection of Lycopodiums grown in large pans, all of them admirable examples of high finish and skilful culture.

At the further end of the tent a noble group of Rhododendrons gives a rich mass of colour, and forms a pleasant and appropriate finish to the scene. The side stages contain many interesting groups, one of the most instructive of which is a fine collection of Begonias from Messrs. J. Laing & Co., Forest Hill Nursery, of which the most striking were Hon. Mrs. Brassey, deep glowing scarlet; Admiration, bright scarlet; L'Abbé Froment, bright yellow; Commodore Foot, a dwarf variety with very deep rich scarlet flowers and dark green downy foliage; Pollie, of a lovely pale primrose hue; Annie Laing, deep pink, very large flower; Mrs. Laing, with large handsome flowers of fine form; and Esther, with magnificent double flowers, rosy crimson, and with the edges of the petals charmingly fimbriated. Then we have examples of cereals from the garden of Dr. Siemens, grown under the influence of the electric light, and which from all being in full ear, and the Wheat having already blossomed, would certainly tend to prove an acceleration of growth and early maturity from it. An attractive example of double white Mignonette, bearing the wonderful name of *Reseda odorata flore-pleno prolifera alba*, from Mr. W. Balchin, Western Road, Brighton. This is really an acquisition, the flowers being very double, each one having the form of a ball of delicate filaments, and it is deliciously fragrant. A basket of seedling Anthuriums from Mr. Walker, gardener to B. H. Collins, Esq., Dunorlan, have scarlet spathes of extraordinary size and substance. An attractive collection of cut blooms of Clematis, plants of Japanese Maples, Ferns, and a charming bit of rustic work, consisting of old tree stems, over which trailed a collection of rare sorts of Ivy, interspersed with moss and various plants in the most natural manner. Of plants worthy of especial attention the Gloxinias from Mr. Walker deservedly merit prominent notice, the flowers being unusually large, well formed, and highly coloured.

Orchids grown by Mr. Myles, gardener to F. Harris, Esq., M.D., Lamberhurst, were very fine; an example of *Cypripedium caudatum* was especially good. *Croton angustifolius* some 7 or 8 feet high shown by Mr. Pope, gardener to J. J. Barrow, Esq., Holmewood Park, Tunbridge Wells, and *C. variegatus*, attracted much attention. A huge *Latania borbonica* from Mr. Buchanan, and an Anthurium and *Clerodendron fallax*, very fine and highly finished, were exhibited by Mr. Bolton, gardener to W. Spottiswoode, Esq., Combe Bank, Sevenoaks. A fine example of *Dipladenia Brearleyana* was exhibited by Mr. A. Gibson, gardener to J. F. Burnaby Atkins, Esq., Halstead Place. A noble plant of *Francisea calycina major*, one mass of bloom, was sent by Mr. Bolton; and several pans of Lycopodiums, each some 2 feet and upwards in diameter.

#### COMPETITIVE CLASSES.

*Orchids*.—The principal group of these charming plants, to which the first prize was awarded, was from Mr. Thomas Denny, gardener to Sir William Marriott, The Down House, Blandford, Dorset. All of these were well-grown medium-sized plants, exceedingly well flowered, and, like all the other plants, they gained much in effect from the tasteful manner in which they were arranged; several fine plants of *Adiantum gracile* being mingled with the front plants, a huge specimen of *A. farleyense* making a noble centre, while high overhead huge Tree Ferns spread their graceful fronds outwards over the group, imparting an air of grace and finish to it. The finest plant of the group was *Lælia purpurata* with twenty flowers. To this plant was awarded a special prize by the Judge, Mr. Dominy, as the finest specimen in the Show. *Cattleya gigas* was especially fine and well coloured. *C. Mossiæ*, too, was well shown in several varieties. The high-coloured *Masdevallia Harryana* told well among the lighter-coloured varieties, and *Dendrobium infundibulum* was very beautiful. Suspended above the large *A. farleyense* was a basket of *Utricularia montana*, very full of its lovely delicate white flowers. A smaller group of Orchids was shown by Mr. T. Myles. *Lælia majalis*, which had been grown in a cool house, had a fine flower. The *Cypripedium* already noted was in this group. A point of considerable merit in these Orchids was the high degree of excellence to which they had been brought in very small pans, the clean vigorous appearance of all of them reflecting great credit upon Mr. Myles.

*Grapes*.—There were three exhibits of black Grapes, three bunches

each; Mr. J. Allan, gardener to G. Hanbury Field, Esq., Ashurst Park, gaining the cup. For three bunches of white Grapes the cup was awarded to Mr. J. Bolton, gardener to W. Spottiswoode, Esq., for some noble fruit of Duke of Buccleuch. There was no competition for this latter prize, but those shown were certainly worthy of the award.

*Asparagus*.—First class—Gardeners, for sixty heads. First Mr. C. Haycock, gardener to Roger Leigh, Esq., Barham Court. Second Mr. Dixon, gardener to Captain Taylor, Glenleigh, Hailsham. Third Mr. Allan, gardener to Lord Suffield, Gunton Park. Market growers, for three hundred heads, Mr. A. J. Harwood, St. Peter's, Colchester, was first. These were magnificent heads, being of very large and even size, greatly superior to all the other exhibits in every class. For the special prize, confined to market growers in Kent, for two hundred heads a first prize was awarded to Mr. Charles Philpot, Eassey, Sandwich.

On Tuesday the Prince of Wales visited the Show, devoting some time to an inspection of the horticultural tent, where he was received by the Hon and Rev. J. T. Boscawen.

#### HARDY FRUIT GARDEN.

WHERE established Apple and Pear trees have been headed down and regrafted during the present spring, the scions will, if they have taken, now be growing vigorously, so that the clay may be removed, and the ligatures of bast or other material with which the scions have been bound may be slackened, and to prevent them from being broken off they must have supports to keep them in position. Thinning Apricots should by this time have been finished, as the fruit is now large, and any that remain more than is necessary for the crop will cause danger in stoning, or should the fruit pass this satisfactorily it will not be nearly so large nor so good in quality. The leading shoots of these where required for filling vacant space should now be tied or nailed in, and the foreright and other shoots not required for training-in may be stopped at the third or fourth leaf, so as to induce the early formation of short-jointed spurs, which are essential for the production of next year's crop. When the trees are well furnished with healthy growths this is a good time to remove any barren wood or projecting spurs. Grubs must be well looked after and rolled-up leaves removed, otherwise this pest soon seriously injures both foliage and fruit. Complete disbudding Peaches and Nectarines, and tie-in the shoots at the base if on a trellis, or lay-in the young wood with small twigs across the branches. Avoid overcrowding, and pinch the shoots at the third leaf to attract the sap to the fruit, and to one leaf afterwards as produced. The trees are generally very healthy this season. Remove blistered leaves, and if aphides appear apply tobacco water, and wash well with the garden engine. Dessert Cherry trees against walls may be treated similarly to Apricots. Plums require all foreright and other shoots not needed for extension to be stopped at the third or fourth leaf, so as to induce the early formation of spurs, similar remarks applying to Pears; and if any of these trees have barren projecting spurs now is a good time to shorten them, provided always there is otherwise a proper supply of healthy wood. Lay in as much young wood of Morello Cherry trees as will uniformly furnish bearing wood for next season. If aphides attack Cherries and Plums syringe them with tobacco water or some approved insecticide. Wall trees generally in restricted borders should have thorough supplies of water, employing liquid manure for weakly trees, and mulch the roots with short, partially decomposed manure. The water and mulching is particularly necessary for trees that have been recently lifted and root-pruned. To enable Strawberries to swell off well copious supplies of water must be afforded, mulching to keep the fruit clean and the roots cool and moist. To secure superior fruit for dessert the trusses should be well thinned as soon as the best fruits are discernible, leaving three or five fruits to each truss, tying them to small sticks. Pyramid and bush Apple, Pear, Plum, and Cherry trees, also cordon and espalier-trained trees, must have attention in watering or supplying with

liquid manure if necessary, and mulching with short manure or other rich compost. Pinch the shoots as soon as three or four leaves are formed, rubbing off any strong growths, and stop extensions at the sixth leaf, the leaders of pyramids being stopped when 12 inches of growth is made. Train in the extensions of cordons and espaliers their full length, and stop the central shoot of those trained horizontally at 12 inches of growth. Raspberries must have the suckers that spring from the stools reduced, reserving about six of the strongest to each. A mulching of manure or an application of liquid manure will be highly beneficial in improving the size, quality, and continuance of this fruit. A similar mulching to Gooseberries and Currants would be found advantageous to the crop.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—Trees with fruit swelling should be well watered and the border mulched so as to maintain an equable condition of moisture at the roots, and a genial condition of the atmosphere may be secured by keeping the surface of the borders well damped. Syringe the trees twice a day so as to have the foliage perfectly free from red spider when the fruit commences ripening. Attend to ventilation early in the day, and lose no opportunity of securing a free circulation of air. In late houses the shoots must be tied down as they advance, stopping all lateral growths to one leaf, and allow no more shoots to remain than can have full exposure to light and air. Directly the fruit has stoned in succession houses the final thinning must be performed, not leaving more than a fruit to every square foot of trellis covered with growth. Remove any leaves that shade the fruit too much, and raise the fruit by means of laths across the wires, so that the sun and air may colour them. When all the fruit is gathered in the earliest house admit air to the fullest extent, and after a fortnight of this treatment it will be advisable to take off the roof lights altogether, syringing forcibly to keep down red spider. The current year's bearing wood not being extensions should be cut out, and where the growths are crowded thin them, allowing no more to remain than will give bearing wood for next year at 12 to 18 inches distance.

*Figs.*—Continue attention to the instructions recently given until the present crop of Figs is fully perfected, when it will be necessary to gradually produce a more genial condition of the atmosphere to accelerate the second crop of fruit. Syringe the trees twice daily, damp the house, and water the border when needful, mulching if not already done. Attend to stopping, tying, and regulating the growths, and by no means allow the latter to be overcrowded. Thinning the second crop should be attended to in good time, and unless the trees are very vigorous it should not be done sparingly, as too heavy a crop is not only exhausting to the tree but the fruit is inferior in size and quality. Early-forced trees in pots in a weakly condition should have the fruit entirely removed, retaining the trees in the house until the wood is well matured, when they may be placed outdoors in a warm situation, and if well mulched and watered they will be in excellent condition for early forcing another season. The pots should be placed on a bed of ashes and be surrounded with the same, syringing overhead occasionally during hot dry weather. Later-started crops will now be rapidly approaching maturity, and when the fruit commences ripening they must have the same treatment as advised for the early-forced Figs—i.e., syringing must be discontinued and ventilation secured.

*Pines.*—Plants that were transferred about last September into the pots in which they are intended to fruit will now be showing signs of fruiting, but if such is not the case bring the plants together and subject them to a comparative state of rest for the next five or six weeks, lowering the heat at the roots to 75°, maintaining a free circulation of air whenever the weather is favourable. Artificial heat will hardly be necessary, but it must be resorted to, to prevent the night temperature falling below 60°. Water must not be withheld, but whenever a supply is needed afford it liberally. The small suckers which were kept in small pots during the winter months should be kept growing until the pots are well filled with roots, when, if necessary, they may be subjected to the treatment advised for the larger plants, and these will afford a successional supply of fruit.

#### ORCHARD HOUSE.

The different kinds of Apricots, Cherries, Peaches, Pears, Plums, and Nectarines are now fairly set, and should be syringed every evening unless the weather is unusually cold. The syringing is indispensable for the Peach, Nectarine, Cherry, and Plum for some time to come; the other kinds of fruit trees are less liable to attacks of aphides. The syringing if forcibly done will mostly be effectual, but on no account must the aphides be allowed to exist and spread, recourse being had to fumigation or the application of an insecticide. During fine weather the ventilators should now be open from 6 A.M. to 6 P.M., affording abundance of water to trees planted out as well as to those in pots. Thin-out the fruit of Apricots if necessary, also that of Peaches and Nectarines; attending to this matter with respect to Cherries, Plums, and Pears, a moderate crop of fine fruit being every way preferable to a heavy crop of inferior quality. Trees in pots should have a top-dressing of rich material, and those planted out should have a surface-dressing of decayed manure. Attend to stopping irregular growths.

#### PLANT HOUSES.

*Orchids.*—Ventilation must be attended to so as to have the foliage of the plants dry about the middle of the day, being careful not to allow a current of cold air to come in contact with them. If any disease is noticed lose no time in examining the roots, cutting away any diseased parts, and apply a little quicklime, keeping the plant drier for a few days. Phalenopses grown in pots or baskets should have very little moss, as the roots delight to cling to the pots. An ordinary greenhouse during the summer months is more suitable for *Dendrobium nobile*, *Laelias acuminata*, *albida*, *autumnalis*, *furfuracea*, and *majalis*, than the Mexican house, as, unless exposed to sun and air, they do not flower freely. Plants of *Laelia cinnabarina* may be top-dressed or repotted as necessary before starting into growth, using rough peat and giving plenty of drainage, watering freely after growth is fairly started. They do best at the coolest end of the Cattleya house. Epidendrums must have plenty of air, and expose them to the light as much as possible. Plants of *Calanthe vestita* that have filled the pots with roots may be shifted into larger pots, employing leaf soil and well-decayed manure, or if not desirable to repot them afford weak liquid manure at every alternate watering. Syringe morning and evening freely, and grow them in plenty of light, keeping the foliage free from scale by sponging.

*Store.*—Winter-flowering plants are apt at this season to receive a check from inattention to their requirements through the pressing demand for immediate attention in other departments, but whatever check the plants now receive will be injurious to the flowering. *Gesnera cinnabarina*, *G. exoniensis*, *G. zebrina*, and *G. zebrina splendens* are amongst the most useful of winter-flowering plants, and must be encouraged to make stout sturdy growth. A single strong corm is best for a 6-inch or 7-inch pot, and for a 9-inch pot five to seven may be employed. It is essential that they be as near the glass as possible, with only sufficient shade to prevent scorching. *Euphorbia jacquiniæflora* cuttings inserted some time ago are now ready for transferring to 4-inch pots, employing fibrous loam. Old plants that have been headed down and repotted should be encouraged to grow, stopping to induce them to branch freely. *Eranthemum pulchellum* is valuable for its blue flowers, and though they are not very durable in a cut state, it is often made worse by not being grown in full light. Spring-struck cuttings should be shifted into 6-inch pots, employing equal parts of loam and peat with a liberal admixture of sand.

#### SWARMING.

THE swarming of bees well understood appears to a thoughtful mind singular and wonderful. The more the insect world is studied, and the farther the researches of men extend into the habits and instincts of insects, the more wonderful their history becomes; but where in the realm of Nature can we find a parallel

case to the swarming of bees? Careful preparation is made in a bee hive for an increase of population, for emigration and colonisation, and for placing a queen over every colony. During the spring months steady progress is made till the crisis of swarming is reached. The hive becomes crowded to excess; fanning is resorted to, to save the community from suffocation; and even while the fanning process goes on bees may be seen coming to the door and on to the flight board for fresh air. A glut of honey may come, giving the bees less room inside; a change in the weather may render the inner life more unbearable and cause clustering outside. These indicate the approaching crisis of swarming. The moment arrives and the rush commences. The bees, with rations for three days' keep, run to the point of the flight board before they take wing, and when on the wing what a noise they make, whirling and twirling above and around their hives! Attempts to swarm without making a great noise would be a failure; for by noise bees follow one another, keep close together, and gather into a cluster on a hedge or tree. About two-thirds of the bees of a full hive go with the first swarm and never return. The bees with the old queen bid a final adieu to the old hive, and those left in the old hive are more comfortable and better off without their old companions. Though without a queen, they contentedly await the birth of a princess. She has rival sisters which come to maturity about the same time and covet the high position of the first-born, and in every encounter between queen bees the result is fatal to one of them. If the bees wish to send off a second colony they endeavour to prevent encounters between young queens by keeping the reigning queen from attacking her sisters in their cells, allowing all to pipe and bark at one another for three full days as much as they like. If the bees determine not to swarm, piping is prevented and the supernumerary queens are killed. This is a brief and well-known story of what takes place in swarming.

That it is natural for bees to swarm all apiarians admit; and, in our opinion the day is not far distant when advanced apiarians will consider that, in the profitable and successful management of bees, the swarming system should be generally carried out. I say generally, for in very unfavourable seasons and under special circumstances and aims wise bee-keepers alter their plans and modify their practice. The exception, however, is not the rule. The more I practise bee-keeping and consider the subject, the more I am convinced that the swarming system of management in competent hands is the best for profit to bee-masters, best for strength of hives and health of the bees.

The readers of the *Journal of Horticulture* have been frequently told that if they make their hives doubly strong with bees in autumn they cannot well fail to be successful bee-keepers or to obtain swarms, and with these in fine seasons they may have large harvests of honey. Large hives made strong with bees in autumn is the shortest and easiest road to the highest excellence in apiculture.

Swarming generally commences in May and continues till the end of June. In Scotland swarming is permitted to continue for eight or ten days in July, but there, and also in some parts of England, Heather abounds, which lengthens the honey season till September. Circumstances and the aims of the bee-master must determine when swarming should end and supering commence. The taking or rejection of second swarms is a point that should be decided by the bee-master, for he best knows the size of his hives and the locality around them. From large early swarmers we have found that second swarms are an advantage, and from later swarmers a disadvantage in our localities. In sending off second swarms about half the bees go with the swarms and half remain in the old stocks. Second swarms from large hives weigh about  $3\frac{1}{2}$  lbs. each; from small hives about  $1\frac{1}{2}$  lb. each. First swarms from small hives are proportionately larger than from large hives—that is to say, that though second swarms from small hives are, generally speaking, not half so large as those from large hives, the first swarms from the former come to within about one-third of the size of swarms from large hives. This is not easily accounted for. The reason may possibly lie in the fact that clustering outside before swarming is usual with small hives—not so with large ones, which swarm without clustering as a rule.

After the queen and first swarm have left a stock the brood nearly filling it continues to be hatched into bees daily for three weeks. Thus there is a great increase of population and sometimes a decrease in weight—always a decrease in weight if honey be not gathered enough to make good the loss of weight in brood. But the cells which yielded the brood are empty, making the effective strength of the population great for work. In such hives there are both store-room and workers. Why, then, turn the bees out and put them into an empty hive to begin house-keeping and comb-building again? Why recommend a practice so against

reason? Well, this practice does seem unreasonable, and I dare not argue the matter. Still, I follow the practice when my stock hives are heavy enough to yield 20 lbs. of honey each on the twenty-first day after swarming, for 20 lbs. of honey realise 25s., which to me covers a multitude of defects in practice. Twenty-five shillings per stock hive at the first harvest is an agreeable profit. Then, in such seasons the swarms, two or more per stock hive, are working in hives with young combs, and the old combs all melted down. To dispose of old combs with advantage is a great satisfaction to me. How it is, let doctors tell, that swarms work, as a rule, harder than stock hives, and bees in young combs do better than in old ones. The fact only is noted here. The other fact, too, is worth remarking—viz., the introduction of comb foundations for the use of swarms, and the creation of natural combs in swarm hives by feeding for a few days when they first enter them. A good beginning may be thus made at the cost of a trifle of the 25s. per hive profit alluded to.—A. PETTIGREW, *Bowdon, Cheshire.*

#### DRIVING BEES IN SITU.

I WAS much gratified to find in the *Journal* of the week before last that you purposed giving the questions asked as well as the answer, as I have often wished to know what they were; and, indeed, it would make the *Journal* doubly useful, and I hope you will continue it when space will allow. I now want you to be good enough to let me know whether, in driving bees from a flat-topped hive instead of turning up the hive and placing it mouth to mouth with another, I could not take out the bung at the top, place the empty hive over, and so drive the bees, as it would be much easier to do?—CLIFTON.

[It is the nature of the bee to store her honey above the brood, or far from the entrance to her home. The reasons for this are two at least. 1st, In winter the warm air rising from the cluster always keeps the honey at such a temperature that the cells can be opened and appropriated, howsoever intense the cold without may be. If, on the contrary, the honey were below the bees, the store would instantly chill and benumb the owners if they attempted to touch it. 2nd, The honey is far from the entrance to save it from plunderers; and leaving man and the bee itself, the chief of these, out of view, we find figuring here rats, mice, wasps, ants, and a host of other creatures large and small that would be quite willing to profit by such an arrangement as would allow them to get the honey first and meet its defenders afterwards.

When assailed the bee rushes to the entrance to meet the enemy, but when frightened it retreats upwards to get at its store and fill its honey bag. In driving the agitation of the comb produces terror, and a rush upwards is the result; but by inverting the skep to be driven, the instinct aforesaid, instead of conducting the insects to their store and giving them cover and security amidst their combs, puts them at our disposal. Our correspondent is quite right in supposing that if we can open a hive above driving is possible without inversion. Mr. Cheshire has, in one of his books, related how this was put to the test in the case of a Woodbury hive which had cross-built combs. To lift out any frame by itself was impossible. The cover was removed. An empty Woodbury minus floor-board took its place, and now drumming on the side soon sent the bees aloft, and the forced swarm remained on the stand, while in the absence of the bees the combs were cut out, straightened, and replaced. But although this was accomplished, the simple removal of the bung will not make its repetition possible with the skep. The combs are fixed to the roof, and the bees between the side combs will at their ascent find no exit, so that but a portion only will be secured. Again, the heavy honey at the top of the skep will by the rapping be by degrees detached, and the comb will probably drop in confusion, to the ruin of the colony our correspondent desires to secure. But if this disaster does not follow, the queen, if not in the centre to which the bung-hole opens, will simply wait against the hive top as under a bomb-proof while the bee-keeper's artillery is attacking the walls. In driving a skep a few weeks ago we cut off the side of the house of straw, removed and transferred to frames more than half the combs, and not till then did we find the queen, gummy with honey, hiding in the recesses of the bung-hole, in which she had no doubt passed her time during each driving. This, which is not a very uncommon case, shows that if some cover can be found by the queen we are unlikely to secure her; this being so, the chances of success in the manner our correspondent suggests are but meagre. The whole process, as ordinarily conducted, is so easy that to attempt it is to succeed, and we therefore counsel that the hive be inverted, and that by preference open driving be adopted, when

the harmlessness of the frightened bees will inspire courage for future operations.]

### TRADE CATALOGUE RECEIVED.

R. Van Til & Company, Hillegom, near Haarlem, Holland.—*Wholesale Catalogue of Dutch Flower Roots.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**To our Readers.**—Although we have printed additional pages, owing to unusual pressure on our columns this week, the publication of many valuable articles in every department of this Journal must be deferred to a future issue.

**Books (Agent).**—The work you name is very full and practical, and in all probability will answer your requirements. Vine culture is included in it, but on this subject you may advantageously procure Mr. William Thomson's work on the Vine, published by Blackwood; and the "Vine Manual," published at this office, post free, 3s. 2d.

**Caterpillars on Roses (M. E. H.).**—We are not aware that you can destroy them by syringing either with pure water or an insecticide. Rosarians find the only true remedy is to examine the trees frequently, and either remove the caterpillars or crush them with the fingers. They are most destructive, and if not attacked in good time and persistently, often quite ruin the blooms and seriously injure the plants.

**Erecting a Greenhouse—a Dispute (An Enthusiast).**—The case which you have submitted, and endeavoured to do so clearly, is one for your solicitor to advise you upon. Even if we were acquainted with all the facts, so that we could fully understand the case, there is still the legal question, upon which we could not venture an opinion.

**Begonias Damping (C. D.).**—You do not make it clear whether the flowers or the plants are decaying; but at any rate the moisture is excessive and the ventilation deficient, and the remedy is obvious—increase the one and diminish the other. Your other question will be answered next week.

**Mildew on Gooseberries (Mrs. A. G.).**—The Gooseberry bushes are infested with the fungus, and we cannot suggest a better or safer remedy than syringing them thoroughly, and then dusting when wet all the affected parts with flowers of sulphur; this will probably destroy the fungus, and the sulphur can be easily washed off the fruit before it is used.

**Planting Lily of the Valley (H. T. H.).**—During fine weather in autumn, or early in spring, before the crowns commence swelling, you may either dig up the whole bed and replant the crowns in small patches in fresh soil, or take out patches from the beds and plant them, placing manure in the spaces made by the removal of the plants: indeed the entire bed should be mulched with manure. There should be spaces of at least 6 inches from patch to patch in both the old bed and the new. If you require very fine crowns and flowers instead of a dense mass of Lilies, twice the space named should be afforded the patches. The ground between the plants should be thickly covered with manure, which should remain throughout the summer months. The plants are partial to a rather shady position.

**Green Glass for Plant Houses (F. R.).**—Green glass may be used advantageously for glazing ferneries and houses for similar plants requiring constant moderate shade, but for other houses we do not recommend it. Most plants require all the light that can be afforded them in our latitude, and the advantage of employing clear white glass is that shading material can be applied when the sun is too powerful and withdrawn when the weather is dull, whereas green glass causes a constant obstruction of the rays of light, and induces a weak etiolated growth. We know a large establishment near London where the disadvantages of coloured glass have been fully experienced, and several houses have been entirely reglazed in consequence.

**Watering (Mrs. Wilson).**—It is far better to supply water to your flower beds in the evenings of hot days than in the morning. If you have only cold spring water and cannot expose it to the sun and air for several hours before using, daily sprinklings will do more harm than good. Stir the soil and form cavities round each plant, then give a copious watering; in the morning as soon as the soil commences drying run a small hoe through it, or the surface will become a network of fissures, through which the moisture will escape and also the heat from the soil. One good watering followed by a mulching, covering the soil with cocoa-nut refuse or manure, will be of more benefit than ten light applications of water without the mulching.

**Cutting Asparagus (A Gardener).**—There is not a doubt that many Asparagus beds have been weakened by continuing the cutting too long in the season, and severing every portion of the growth from the beds. It is on the strength and maturation of the growths in summer that the quality of the produce in spring depends; hence it is wise to apply liquid manure to the beds during July and August, this practice being more effectual than thick coverings of manure in the winter. You will adopt a wise course by producing a

full supply of Peas of the best quality as early in the season as possible, and you will probably adopt the most practical mode of preventing the too close cutting of the Asparagus.

**Low Temperatures for Grapes (Doubtful).**—There is no doubt whatever that Grapes have set freely in a minimum temperature of 50°. We have for years had fine and full sets of Black Hamburgs when the temperature on many occasions was as low as 45° when the Vines were flowering. This, however, was not by preference, but the consequence of what many might term defective heating appliances; still, as the crops were invariably satisfactory the defect indicated was not admitted, and it was not deemed necessary to incur the cost of alterations when good results could be produced without them. More failures occur in setting Grapes by injudicious ventilation and other errors in management than by the fall of a degree or two in temperature from the regulation high standard of 70° for Muscats and 65° for Hamburgs.

**Double Canterbury Bells (H. P.).**—The flowers have a multiplicity of corollas, hence appear to be double, but as the organs of fructification are perfect the plants will produce seed. We have seen, and in fact grown, many almost or exactly similar, and have saved seed from the plants and raised seedlings. If, however, we have desired to perpetuate any particular variety we have removed the spikes immediately the flowers commenced fading and secured fresh growths from the base. You can adopt either or both the modes we have suggested. We prefer single flowers, and the calyx transformed into petals, or the variety known as Campanula Medium calycanthema.

**Raising Cinerarias (Civil Service).**—The fact that you have no hotbed need not deter you from raising plants from seed. At this season of the year no artificial heat is needed, and seedlings may be raised better in a cold frame or even in the open air. If you place 3 inches of light soil in a box that is 5 inches deep, water it well, sow the seed thinly, cover it very slightly, and lay squares of glass over the box, placing it in shaded position in a cold frame, or stand it behind a wall having a north aspect, the seed will germinate freely provided the soil is always kept moist. As the seedlings grow the glass must be propped up, and great care taken to prevent the depredations of slugs, which eat the young plants voraciously whenever they find them.

**Cherry Trees Gummed (J. P., Dublin).**—The shoots sent afford evidence of severe gumming, which has been unusually prevalent during the last two or three seasons, and although the cause is unknown it is generally attributed to a severe check of the sap in the early period of the growth, also to immaturity of the wood. We have trees of various kinds of Cherries against a wall 100 yards long which were previously trained to an open trellis of woodwork, and when in that state they gummed very badly. They were root-pruned and some lime rubbish mixed with the soil, spreading it on about 6 inches thick, and mixing it with the soil to a depth of about 18 inches. This was done over ten years ago, and the trees have been healthy ever since, annually producing very fine fruit. We should in your case take out a trench about 3 or 4 feet from the stem according to the size of the trees, cutting off all roots extending beyond that radius, and in filling up employ some mortar rubbish with the soil to the extent of about a tenth, and working in some of the same towards the stem as far as can be done without disturbing the roots too much. This should be done early in autumn.

**Peach Mildewed (Idem).**—The fruit sent is badly infested with mildew. Apply flowers of sulphur, giving the whole tree and fruit a thorough dusting. Syringe the curled leaves well and frequently with tobacco water, the foliage being no doubt infested with aphides. In the autumn have the trees carefully lifted, shortening back some of the strongest roots extending beyond 4 feet from the stem, preserving as many of the small fibres as possible, especially near the stem.

**Foreing Vines (J. A.).**—Your proposed plan is a good one. A year's rest after long foreing, still starting the Vines sufficiently early for the wood to be matured in the autumn, coupled with lighter cropping, would be of great advantage to the Vines. If manure has been applied to the border yearly a heavy dressing of lime would probably be highly beneficial, spreading it on the surface and letting it remain for a time to be slaked, then pointing it in carefully with a fork. If no manure has been applied we should first remove with great care the surface soil, and after giving a covering of turfy loam and bones, with a liberal addition of wood ashes, then give a thick dressing of good manure, and permit it to remain and decay. This would encourage surface roots, and at the same time afford wholesome food for the Vines. As you have won prizes with your Grapes you will be fully aware of the importance of training the laterals sufficiently thin, that the foliage can be fully developed and each leaf exposed to the direct influence of the sun.

**Pear Leaves Blistered (Kilferman).**—The leaves are infested with the Pear tree blister moth (Tinea Clerckella), which deposits its eggs in May and June upon the foliage; and the larvae, immediately they are hatched, penetrate beneath the cuticle, and by feeding upon the parenchyma cause brown blisters which ultimately become black, and the leaves so affected not unfrequently fall. The insect is full grown in September, and the maggot lets itself down to the ground, where it spins itself a cocoon on a leaf, changes into a chrysalis, and remains as such until the following season. The best remedy is to remove all dead leaves in autumn and burn them, being careful to gather them frequently as they fall, and dispose of them as collected. From the beginning of May the trees should be washed two or three times a week with a solution of soft soap, 3 ozs. to the gallon of water, applying with a syringe, and continuing until the middle or end of June. Nicotine soap at the rate of 3 ozs. to the gallon would be more effectual than the soft soap.

**Exhibiting Kidney Beans (Ignoramus).**—The Dwarf Kidney, or so-called French Bean (*Phaseolus vulgaris*) and the Scarlet Runner Bean (*Phaseolus multiflorus*) are not only distinct varieties, but distinct species; but we doubt if they can be regarded as distinct kinds for the purposes of your exhibition. If the schedule designates "kinds," we assume that only one dish of Kidney Beans are admissible; and if "varieties" is the term employed, the committee may still mean the same, yet a collection including a dish each of dwarf and runner Beans could not properly be disqualified. We should only exhibit one dish choosing the variety that affords the best pods at the time.

**Management of Fruit Trees (J. M.).**—As the trees have been planted three years and grown so luxuriantly we presume they have reached the top of the fence, and in that case recourse must be had to root-pruning to check their vigour and induce fruitfulness. Merely shortening the branches without restricting the roots will be of no avail, as such a course is always followed by strong growths that are in their nature essentially fruitless. The aspect is suitable for your trees. Possibly the growths have been too crowded. The branches should be so thinly disposed that the leaves of one do not overlap those of another. The breastwood should be shortened now, leaving four fully developed leaves on each shoot, all subsequent growths to be pinched to one leaf as they are produced. If the branches are too numerous for training to the trellis

in the manner we have suggested you may remove some of them at once, leaving those that appear the most firm and short-jointed, at the same time endeavour to form a fair-balanced tree. In October or early November, assuming that the trees cover the fence, they may be root-pruned by partially or entirely digging the trees up according to their vigour. Replanting often has a magical effect in promoting fruitfulness; at the same time we think it should not be resorted to when the trees are very small, unless indeed toy trees are required. For purposes of utility we like the trees to attain a good size before checking the roots, as they are then in a condition to produce crops of substantial value. If you require your Cox's Orange Pippin to be dwarf, dig it up and replant in the autumn; if you want as much fruit as possible, thin out the branches well now so as to admit the sun and air to mature those remaining, which should not be shortened except for the purpose of maintaining the symmetry of the tree. After a tree is newly planted and the roots placed near the surface there is no method of keeping them then equal to mulching with manure and not digging round the trees. The moisture attracts the roots to the surface, and the want of it there causes them to strike downwards. Firm soil, too, promotes the emission of numerous small fibres, which conduce to a tree's fruitfulness, light and deep soil encouraging strong fibreless roots and growth correspondingly luxuriant.

**Names of Plants (G. M. N. C.).**—The specimen, which arrived in an envelope and completely crushed, was unrecognisable. (S. B.).—1, *Cattleya Mossiae*; 3, *Begonia semperlorens*; 2 and 4 were withered. (J. B.).—The specimens were greatly withered on arrival, owing to their being in the post during Sunday, but the following were recognisable:—4, *Coccoloba platyclada*; 5, *Cyperus alternifolius*; 6, *Plumbago capensis*. (H. E. B.).—*Pyrus Aria*, the White Beam Tree, incorrectly called the Service Tree in some parts of Lincolnshire. (Winchester).—We are unable to recognise the specimen, which was injudiciously sent in a letter and consequently quite crushed. (C. F.).—The plant to which your refer is *Chrysanthemum frutescens*; the yellow form is *Etoile d'Or*. The specimen sent is apparently an *Ornithogalum*, but too much injured for determining the species. (Philanthus).—The specimen appears to be a portion of a spike of the peculiar *Muscari plumosum*, a variety of *M. monstrosum*, which resembles the forms known to the old writers, Parkinson and Gerard, as *Hyacinthus comosus*.

**The Hive of the Busy Man (Aptarian).**—We are obliged to you for your letter. Our review of Mr. Bartrum's manual is in type, but space cannot be found for it this week.

#### COVENT GARDEN MARKET.—JUNE 8.

BUSINESS remains steady; all classes of goods being cleared and prices well maintained.

#### POULTRY AND PIGEON CHRONICLE.

##### AGRICULTURAL IMPLEMENTS AND MACHINERY.

DIFFERENT periods of the year bring a change of seasons, in which the use of certain implements and machinery come into almost daily and constant use upon the home farm. The extent, situation, soil, and climate will each naturally oblige the home farmer to select and use such kinds of implements and machinery as may be best, most economical, and effective in work upon the land. Our remarks must be considered as more especially offered for the direction of those who are learners and beginners in agricultural management, although we shall occasionally have to introduce to notice entirely new or improved articles well worth the

attention of farmers of considerable experience. In consequence, however, of the multiplicity of the alterations it requires great caution and discrimination on the part of the home farmer in deciding what is really an improvement in his own case, according to the size of the farm, the soil and climate, situation, rotation of cropping, as well as the proportion of arable to pasture land in his occupation.

We must first give our attention to the drill machinery now offered by different makers. As regards large occupations, we must consider that none of these are so large but they come into competition with still more extensive occupations on some parts of the continent, but especially in America and Canada, where the most ingenious steam machinery is in use. We must in consequence avail ourselves of the best implements of every kind. In referring to the corn drills worked by steam power, W. C. Woolnough & Co.'s patent steam double corn drill demands our first notice, because it is so constructed that it may be taken to pieces and made into two 6-feet horse drills—an important advantage, as the headlands cannot be drilled by steam power. The steering and turning at the land's end are easily effected, and the turn-tables to the travelling wheels prevent the headland being cut up. Harrows can also be attached to this drill with turn-tables, guide irons for wire rope, platform behind, and seats in front for the man steering, and patent chain steerage. These are all-important considerations, for it will enable the work of seeding and finishing-off to be done simultaneously and by one operation, so that in case of change of weather the seed is safely deposited in the land—a practical part of the farming business we have always strenuously contended for in our weekly notice of "Work on the Home Farm."

We now have to consider the most economical drilling machinery to be used by horse power, as we must first notice Messrs. Richard Garrett & Sons' general purpose drill for depositing corn and seeds, with or without manure, and fitted with Chambers' patent manure barrel and scrapers. These drills combine the merits of the Suffolk corn drill with those of the seed and manure drill. They are suited to all requirements, and the firm recommends the use of separate implements as being more convenient upon large farms for the various purposes. We, however, cannot entirely agree with this idea, for it must be a very large occupation which can afford implements for every purpose as a matter of economy. Besides, a large number of implements require extensive sheds or buildings for protecting and storing them in readiness for use. Repairs, too, would be a serious item in either case, and it will depend much upon the care taken as to which plan would entail the greatest cost. The box in which the grain or seed is contained is made separate from the manure box, so that when the drill is required for corn or seeds without manure the whole manure apparatus may be removed. The manure-delivery barrel is made upon Chambers' excellent principle, consisting of a cylinder formed of a series of rings, each having projecting surfaces (for the delivery of either very fine or rough manure), which come in contact with the scrapers placed beneath the box, the pressure of which on the barrel is regulated by adjustable springs to the greatest nicety, according to the adhesiveness of the manure used. The manure box is fitted with a novel and excellent stirrer, which never fails to give a constant and regular delivery from the box to the barrel, however moist the contents of the box may be. It will sow from one bushel to any quantity required per acre, and is so easily adjusted by the slide that even when at work the quantity can be varied according to the quality of the soil and without any change of gear wheels. When required the drill can be provided with Chambers' patent broadcast trough, enabling the implement to be readily converted into a broadcast manure distributor. This must be considered a matter of some consequence when we

know that artificial manure of various kinds, particularly when containing nitrate of soda in combination is used, as it frequently must be to keep pace with adverse seasons, for when either Wheat or spring corn look badly the broadcast application of manure is an actual necessity. When the Clovers and other Grasses require manure as well as the park or pasture land we cannot now find labourers, as we did formerly, who can distribute equally over the land light manures by hand.

A one-horse Turnip and manure drill improved next attracts our notice, because such a machine properly constructed is a very valuable one for various purposes—not only for working on the home farm where but few horses are kept, but also to enable the drilling to be accomplished as fast as the land is ready during the day. At the same time we have found when occupying hilly land that the light one-horse machinery of this kind has lightened and facilitated the work of drilling considerably, either with or without manure. This machine, as described by the firm, is capable of being used for drilling in rows either on the flat or ridge-ploughed lands, Turnip and Mangold Wurtzel seeds, with any kind of light pulverised manures. The drill being very light is the draught of one horse or pony only, and also very convenient and easy of management, being 3 feet 8 inches high, and 4½ feet wide.

We have now to turn our attention to the lever horse hoes and their improvements. Those made to cover a space equal to the width of a full-sized drill are said to be economical, because they accomplish so much work; but we view those which are made to cover so much ground as only suited to light soils, or those in a light and loose condition, or with a crop of Lent corn, Peas, Beans, &c., growing thereon, because we contend that they will not do the work required upon winter-sown Wheat, &c., after the soil is settled down hard except in very light sandy soils. These wide hoeing machines are made lighter than ever to reduce the draught, and they have in consequence less hold upon firm settled land; therefore we do not recommend their use upon winter-sown Wheat, or on any crop where the soil is hard, or hard in patches like much of our mixed soils. In such cases we prefer the ordinary one-horse hoe, of which there are various patterns, but they are generally adapted for hoeing between root crops at varying widths. They should have sufficient strength and substance to be converted either into a light scarifier as well as a horse hoe for every purpose of hoeing all crops drilled at widths varying from 2 feet to 9 inches, and with hoes of a suitable form and strength to enable them to move the soil effectually as well as cutting up the weeds. In various crops—when we find the season adverse and the land hard, with the plants looking yellow and sickly, especially as refers to the Wheat crop—the breaking of the surface is so important that it is upon well-tilled land a matter of more consequence in the aftergrowth of the crop than an extra application of artificial manure. In order to carry out these different operations the new expanding five-tine horse hoe made by Messrs. Woolnough & Co. is well adapted, being exceedingly powerful for all purposes, and is supplied with patent blades, shares, knives, and tines, which can be worked effectually without injury to any growing crops.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This is still of the utmost importance when the work on the land is tillage for roots, or occasionally alternating with labour on the fallows for Wheat. We consider the best time for drilling Swedes for the general purpose of feeding sheep on the land to be from the 8th to the 12th of this month. In the event, however, of early and ripe Swedes being required for cattle as early as possible we have often sown the seed by the 12th of May. For several years in succession when keeping a large summer flock of breeding ewes, as well as feeding a flock in winter, we had a portion of growing Swedes hoed out and singled before the previous year's growth had been all consumed. We have had Swedes in good condition in the land as late as the 18th and 26th of June and the 4th of July. This was, however, during a period when the great value of Mangolds was but little understood. In various seasons we had stacked and thatched all our field Hayricks of the same year's growth before we had finished feeding our Swedes, thus showing that we were fully prepared to meet and contend with late springs and periods of vegetable scarcity; which, however, may now be done better with Mangold, without delaying any corn crops. The fallows for Wheat on the heavy land should not be worked fine, because if occasionally cross-ploughed as the weeds appear in such a season as we have now everything must die, and the land be thoroughly aerated and improved for the production of future cereal crops. In some cases the land intended for Wheat is now covered with luxuriant crops of Tares to be fed off by sheep, and this for outlying land not convenient for dung carting is an excellent preparation for Wheat, especially when the sheep eat a fair proportion of decorticated cotton cake and followed by a backward fallow as fast as the land is cleared of the green crop. This system of folding sheep is an excellent plan in hot weather, for

when field-feeding on grass at daytime they are apt to resort to hedges, ditches, and banks, &c., for sunshade, and thus leave their manure where it does no good. For that reason we prefer folding in the day instead of at night in the hottest seasons. The work for odd horses or single horse work will now prevail, although we approve of a mule or ox for actual hoeing between root crops; yet there is always a large amount of work for stout single horses in the summer time, such as ploughing between the Potato crops where they are planted at a yard apart between the rows, also hilling and second hilling in the lines, as well as single-horse scarifying on the fallows. All this is economically done if the animals are of sufficient weight and power. All the light work, such as horse-hoeing either on the flat or stretch for the Mangolds, early Swedes, Cabbages, Kale, &c., can easily be done by the odd horse, mule, or ox. Paring and burning may now be commenced as fast as the Saintfoin hay is cleared away and the land after burning got ready for Turnips, to be followed by a crop of Turnips fed off by sheep, and afterwards sown with Wheat in November or Barley in March the following year. Horses, too, will in a few days be required for carting the field hay to the stack.

*Hand Labour.*—Men will be required in stacking the hay; but all the heavy manual labour of unloading, &c., whilst stacking hay will now be done by the elevator, so that the dearer hand labour becomes the more we shall see our way to dispense with it upon well-managed farms by the aid of machinery. In stacking hay much judicious care is required to decide when it is really fit to be put into rick to be safe against overheating. When, however, there may be some doubt about this matter, or when rain is pending and the grass nearly dried enough, we recommend layers of good sweet straw between every three waggonloads. If the hay should be required for chaff for horses or fattening cattle the straw, after having performed the office of saving the hay, will also be converted into a valuable feeding material. This is one of the best ways of saving hay; but when it is of fine quality and required for feeding sheep, but lambs especially, it should if possible be put together by itself, and if overheating is anticipated a sack stuffed with straw may be drawn up the rick a little at a time after a load or two is added. In this way a sort of chimney is formed in the centre of the stack, and when finished a hurdle placed over the opening covered with straw for a short time before being thatched will allow the heat to escape, and save the hay. We have, however, saved capital fine herbage of Dutch Clover for lamb hay by turning the rick over, making it up afresh upon a stand adjoining—only involving hand labour; but it must be done at the end of about five or six days, or the second-made rick will not heat sufficiently to be saved from turning mouldy. In order to ascertain whether the rick requires to be turned or not we use an iron rod with a gag at the end, which, after being introduced and left in the rick for an hour or two, a portion of the bay may be pulled out of the rick from any part, showing exactly its condition, and when any danger is anticipated. This is the best plan to enable the home farmer to decide what course shall be taken to prevent damage to the hay.

*Live Stock.*—The fattening bullocks on pastures will now be gaining beef fast, as the grass is healthy and forcing, although not so strong and plentiful as it is in some seasons. Dairy cows, also, are now doing well, for if the grass is rather short it is good in quality. Suckling calves have been offered in large numbers during the past six weeks, and they are likely to pay well as veal this year, for meat importations do not affect the value of veal and lamb as it does beef and mutton, pork, &c. We find fattening calves pay as well or better than milk selling when the farm is inland or away from towns or stations. Ewes and lambs, both in the breeding and fattening, have done well lately, although in various instances food has been scarce; but dry weather is always suitable for the health and fattening of sheep.

## POULTRY AND PIGEONS

### THE HATCHING SEASON.

MR. MUIR, I see, states on page 432 that he finds March eggs hatch better than those laid later on; but as he wishes to know the opinions of others on this subject, I write to say that my experience for several years is the very reverse. I always find as spring advances and the weather becomes milder eggs hatch much better, and I have fully one-third more chickens from eggs hatching in April than in March. Most poultry-keepers have, I believe, found this a very bad backward hatching season, and at first we were unfortunate ourselves, but since March we have had no reason to complain, and have now a fine healthy lot of Dark Dorking chickens.—M. F. SMYTH, Londonderry.

### THE COUCOU DE MALINES.

I HAVE just received from a friend in Belgium the following notes on the "*Poulets de Bruxelles*," known as the Coucou de Malines. He says—"The origin of these birds, according to my

opinion, as well as that of a large number of engraisseurs (or fatteners of poultry), is as follows. About thirty years ago, when Cochins were first introduced into this country, they caused great excitement. All the farmers would have crosses of these birds with our Campine fowls; and these crosses, being repeated with the best subjects produced, became the large breed of fowls so called (de Malines), but really reared in the country between Diest and Beverloo. They are sent poor to the Malines poultry market held once a week, and are purchased by engraisseurs who live in the districts between Malines, Termonde, and Assche. As layers they are not considered the best, but they fatten exceedingly well, and are ready for the table in four weeks. The engraisseurs prefer those without feathers on the legs; they all agree that those fatten more easily.

"This breed has a great reputation as a table bird; so much so that the whole of Belgium, Germany, the north of France, and Holland always send to Brussels when they require large and delicate poultry."

At the last Berlin Exhibition for dead poultry the first prize was given to the Coucou de Malines fattened by a Brussels poulterer.—L. E. WILSON.

### LIVER FOR FOWLS.

SOME little time ago we had a long spell of parching east winds here. Vegetation, which should have been growing rapidly at the time, was at a standstill, and all kinds of insects and grubs which fowls devour with such relish were nowhere to be found. The most inexperienced poultry-keeper knows that the want of these soon begins to affect the hens, especially in the production of eggs, which become scarcer and scarcer until the supply almost ceases. This was the case with my fowls during the period in question, and probably I should have had no eggs until the weather and earth had become humid, had I not, when I saw how matters stood, begun giving a little rawchopped liver daily.

Not more than three or four days after the hens had this they one and all started laying, and did not stop again until rain came, when no more liver was given. I have tried many kinds of flesh food for fowls during such a time, but have found nothing so good as the liver. Their recommencing to lay during the very kind of weather which stopped them, I attribute wholly to the liver, as no other change of food was made. As liver is so cheap and can be easily procured, probably it may be to the advantage of some of your readers to know this, and as we may have much dry hot weather shortly I consider the matter well worth publicity.—J. MUIR.

### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Charing Cross Hotel on Friday the 3rd June. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Rev. J. D. Peake; and Messrs. T. W. Anns, A. Comyns, H. R. Dugmore, J. C. Fraser, S. Lucas, and L. Norris.

NEW MEMBERS.—The following new Members were elected: Geo. Carrington, Missenden Abbey, Great Missenden, Bucks; Mansfield C. H. Mills, Tapton Grove, Chesterfield.

The following new Associates were elected: H. J. Buchan, Wilton House, Southampton; Rev. Henry J. Crockford, Hexham Parsonage near Exeter; Mrs. H. F. Dent, Scruton Hall, Bedale, Yorks; Rev. W. A. Hows, Cold Higham Rectory, Towcester; Jas. Read, High Park, Ryde, Isle of Wight; David W. J. Thomas, Ely Cottage, Brecon; John W. Williams, Mildenhall, Suffolk.

H. A. Silvester, late an Associate of the Club, was elected a Member.

MEMBERS REMOVED FROM BOOKS OF CLUB.—The names of the following Members and Associates whose subscriptions for 1880 had not been paid were, in conformity with the resolution passed at the meeting of the Committee held on the 27th April last, removed from the books of the club.

Members.—Dr. Cameron, Epworth, Rotherham; John B. Compton, Hallyburton, Cupar Angus, N.B.; W. Dalton, Allen Grove, Carlisle; Mrs. J. S. Findley, 2, Alleyne Crescent, West Dulwich; Lieut.-Col. Fludyer, Ayston Hall, Uppingham; Lieut.-Col. Lockwood, Bromley, Harlow, Essex; J. J. Malden, Hill Farm, Biggleswade, Beds; W. Wallis, Jun., Eastleigh, Bishopstoke.

Associates.—W. C. Bland, Forston House, Dorchester; J. E. Bloodworth, Jersey Cottage, Cheltenham; Lawrence Booth, Victoria Road, Chester; W. Champion, Griffiths Town, Pontypool; J. Day, 48, York Street, Luton; W. Gatis, George Street, Luton; S. W. Hallan, Whitwick, Leicester; Benj. A. Hogg, 2, Cornhill, Dorchester; W. J. Johnson, Vortersberg, Cork; D. Lewis, Thornhill Cottage, Carmarthen; A. Ogden, Albion Foundry, Ashton-under-Lyne; Capt. John N. Preston, Flaby Hall, Gargrave, Leeds; W. T. Russell, Bude Lodge, S. Norwood; R. Swift, Southwell, Notts.

OWNERS BIDDING AT SHOWS.—The resolution, of which notice

had been given by Mr. Fraser at the last meeting to the following effect—"That the resolution passed at the meeting of the Committee held on the 28th March last, condemning the practice of owners being permitted by Poultry Show Committees to bid for and buy in their own exhibits, be amended by inserting the words 'of birds entered in selling classes' after the word 'owners,'" was proposed by Mr. Fraser. After considerable discussion an amendment was proposed by Mr. H. R. Dugmore, and seconded by Mr. L. Norris, to the following effect.

"That the resolution of March 28th having been passed in relation to a specific case arising in a selling class, and considerable doubt having been since expressed whether or not the same illegality extends to the open classes, it is resolved that (before either limiting the said resolution to selling classes, or confirming its wider significance) the Secretary be instructed to obtain Counsel's opinion on the whole question."

The resolution proposed by Mr. Fraser having been subsequently withdrawn, the amendment of Mr. Dugmore was put as a substantive resolution and carried.

CIRCULAR TO RAILWAY COMPANIES.—The Secretary reported that he had issued the circular to railway companies directed to be sent out by the Committee, and that he had received answers from nearly all the companies. Several of the letters from the leading companies, which were of a most satisfactory character, were read to the Committee, and answers were directed to be sent to some of them.

CIRCULAR TO SECRETARIES OF SHOWS.—The Secretary reported that he had received a large number of answers to the circular addressed to the secretaries of shows as to the dates at which the several shows were to be held. The Secretary was directed to have a list of the dates of the shows so fixed printed, so that copies of the same might be furnished to the secretary of any show desirous of obtaining the same.—ALEX. COMYNS, Hon. Sec. Poultry Club, 47, Chancery Lane, June 4th, 1881.

The following is a copy of the circular addressed to the secretaries of the various railway companies by the Club—

"I am directed by the Committee of the Poultry Club, a body representing a considerable number of fanciers and exhibitors of poultry throughout the United Kingdom, to draw your attention to the following facts and request your careful consideration of them.

"There are during each season more than 250 shows held in the United Kingdom. In some cases thousands, and in all cases a considerable number of birds, are sent by railway to compete at these shows. The value of these birds is, as a rule, very considerable, and the amount of revenue derived from their carriage by the railway companies cannot but be large.

"From time to time complaints are received by the Committee of the Poultry Club as to the rough and improper treatment of these birds by railway servants. For example: piles of hampers have been seen packed upon their sides on the roofs of railway parcel vans; the baskets containing the birds have been seen to be roughly pulled from the railway trucks, and handled in general with such roughness that the birds must have been dashed against the sides of the baskets. In one case the porters at a junction were seen rolling the circular baskets on their sides along the platform. Tail feathers have been plucked out, and birds thus rendered for a time valueless for exhibition, and notwithstanding the plainest directions on the labels, poultry hampers have been booked by slow routes and otherwise delayed.

"The Committee desire these matters to be brought under the notice of the various railway companies, in the hope that they will, either by giving special directions to their servants by circular or otherwise, take steps to diminish the evils complained of."

### REMARKS.

29th.—Overcast and cooler; few drops of rain, but not a measurable quantity; brighter in evening.  
30th.—Fine, bright, and warm.  
31st.—Fine and hot; very bright sunshine throughout.  
1st.—Hazy morning; bright hot day.  
2nd.—Fine, bright, and hot.  
3rd.—Fine and hot; rather stormy-looking at times.  
4th.—Fine, bright, hot, day; gusty wind and much dust; cloudy towards night.

A very hot week; shade maximum temperature averaged 78.5°, which is about 10° above the average. The temperature rose to or exceeded 80° on fine days. No rain throughout the week.—G. J. SYMONS.

## SPECIALITIES AT SOUTH KENSINGTON.

VISITORS to horticultural exhibitions may be considered as regarding them from two very different standpoints. One section, much the larger of the two, includes the general public, who view a flower show simply as a display of plants which elicits admiration in proportion to the abundance or brilliancy of the flowers and the taste exercised in the arrangement. The other comprises the gardening fraternity, whether competitors or not, who manifest a more critical judgment, and visit an exhibition with the intention of gaining if possible some hints that may be of service to them in their own practice. They desire not only to observe the relative degrees of success obtained by different cultivators, but also the most distinct, useful, and effective plants, whether new or old, that may be advantageously added to the collections under their charge. Thus to a gardener a large horticultural exhibition is both attractive and instructive, and few of those who visited the recent display at South Kensington could have left without having increased their knowledge by some few items of more or less value. Many gardeners, however, were necessarily unable to be present, and these, doubtless, read the full reports that have been published; but as there is much that cannot be fully treated in a report, a few additional observations on the chief features of the Exhibition and the most remarkable plants shown may be welcomed by readers who were debarred from the privilege of personally inspecting the Show.

## HARDWOODED PLANTS.

Those who admire formal training could not fail to be satisfied with the handsome specimens included in the classes for stove and greenhouse plants, as the species and varieties of Cape or New Holland plants which popularly bear the above name have been rarely better represented. There was a most pleasing freshness and vigour noticeable in all the collections, indicating the excellent results that can be attained by careful treatment even with plants that are considered to require more than ordinary skill. Some excellent examples of neat training were also contributed, and for large specimens of slender-growing plants this is a matter of great importance; and though the exact globular style may be obnoxious to some, plants so trained unquestionably possess beauty, though it be of a formal type. However, there is one point upon which most will agree—namely, that hardwooded plants in a small state and untrained are not only ornamental but almost indispensable for greenhouse or conservatory decoration. Groups of these small plants were admired by all, and the healthy free-flowering specimens of numerous species and varieties

in pots varying in size from 60's upwards to 32's or 24's, were all that could be desired or expected in decorative plants. This is undoubtedly the most profitable way to have hard-wooded plants. It does not pay to grow large specimens, whereas those a few years old are of considerable service, and a stock can easily be maintained by purchase, or, where the requisite time can be spared, by propagation.

## ERICA CAVENDISHIANA.

Heaths were not very largely represented, but several of the best summer-flowering varieties were shown, and among them the well-known *E. Cavendishiana* was especially numerous, and in one collection remarkably fine. These were from Messrs. Cutbush & Son, and attracted as much attention and admiration as they received at Regent's Park a few weeks since. The plants, though only in 8-inch pots or even smaller sizes, were notable for their extraordinary vigour, having robust tapering branches of great size and strength, densely clothed with their large, rich yellow, tubular flowers. Very rarely is this handsome and comparatively easily grown Heath seen in such satisfactory condition, and the treatment must have been more than ordinarily liberal to ensure such pleasing results. Many persons are unaware that this useful Heath is a hybrid; yet such is the case, and horticulturists are indebted to Messrs. Rollisson for the production of this among many other forms that originated at Tooting. It was obtained about the year 1840 by crossing *Erica depressa* with pollen from *E. Patersoni*, and strangely combines the characters of the parents, being much more vigorous than the former and erect in habit, but with flowers similar in shape though richer in colour. It received the name it bears in honour of the Duke of Devonshire, and has now deservedly become one of the most popular Heaths in cultivation.

## PYRETHRUMS.

Among summer-flowering herbaceous plants the numerous varieties of *Pyrethrum roseum* deserve a prominent position. Whether planted out or in pots they are very beautiful, and they yield a serviceable supply of flowers with but little trouble. The collections staged at Kensington by Messrs. Kelway & Son and Mr. T. S. Ware well exemplified the progress that has been made with these plants in improving the size, form, and colours of the flowers. The double forms are very attractive; but the general favour was accorded to the single varieties, some of which could not be excelled in brilliancy of rosy crimson tints, while others were unrivalled in the delicacy of the pink or the purity of the white distinguishing the florets. In every case the bright yellow central disk seemed to afford a contrast or relief to the outer ring of colour. That these single forms will grow in favour there can be no question, and they well deserve all the attention they may receive. All the flowers were unusually fine in the two collections named, some exceeding  $2\frac{1}{2}$  inches in diameter, with broad substantial florets forming a head even and circular in outline. Some of the best varieties were the following: In Messrs. Kelways' stand—*Romeo*, bright rosy crimson; *Mrs. Carlyle*, very rich crimson; *Mercury*, clear bright pink; *Boreas*, good pink; and *Albion*, white. In Mr. Ware's stand—*Vivid*, intense crimson; *Ruby*, warm clear crimson; *Morning Star*, fine pink; *Hamlet*, pale pink; *Virginale*, blush white; and *Warei*, very large pure white.

## CRASSULA JASMINEA.

This plant has been already referred to, but it was so well

shown at the great Exhibition that it merits an additional note, as it cannot be too highly recommended for decorative purposes. The plants included in several groups were similar to those previously exhibited by Mr. W. Brown, having heads of white tubular flowers a foot in diameter, and emitting an agreeable fragrance that appears to be very lasting. The flowers, too, are durable; the plant is easily grown, and altogether admirably suited for the conservatory, in which a few specimens are very striking and attractive. Like many of its allies this is a native of the Cape, but it has now been in this country considerably over half a century. It is of easy culture.

#### HARDY CACTI.

One of the most interesting collections of plants out of the competitive classes was the group of hardy Cactaceous plants exhibited by E. G. Loder, Esq., all of which had been collected by himself in the Rocky Mountains at an elevation of 10,000 feet and more. A large number of specimens were contributed, many being in flower, and all in excellent health. The two most attractive were *Echinocactus Fendleri* with large bright rosy flowers, and *E. gonacanthus* with bright orange blooms; but the others having chiefly pink flowers were also noteworthy. The species of *Echinocactus* were *E. Simpsoni*, *E. phoeniceus*, *E. viridiflorus*, *E. viviparus*, and *E. paucispinus*; the *Opuntias* represented being *O. comanchica*, *O. Whipplei*, *O. Missouriensis*, and *O. arborescens*. For the rockery and similar positions these plants are well adapted; and as they are from regions where the temperature at some periods of the year falls very low, they would no doubt prove hardy in any district of England, their chief enemy being excessive moisture.

#### PHILADELPHUS MEXICANUS.

To conclude these notes a brief description of the Mexican *Syringa* or Mock Orange, exhibited by Mr. Walker of Thame, may be admissible. This attractive half-hardy shrub was originally introduced forty years ago to the Royal Horticultural Society's Gardens by Mr. Hartweg, who found it in several districts of Mexico. In the neighbourhood of Jalapa it is said to be cultivated, and it also grows wild in the hedges. It is 2 to 3 feet in height, with ovate leaves and large white flowers of very symmetrical form, and possessing a powerful but pleasant fragrance. Mr. Walker's plant was growing in a pot, and was trained in a pyramidal form to a stake. In the southern counties and sheltered districts it would probably prove hardy, and under such conditions its beauty would be seen to much better advantage than under glass, though the flowers appear to last well.

Such were a few of the specialities among the plants at Kensington, but there were many more that may perhaps receive attention another time.—L. C.

#### A PLEA AND SUGGESTION FOR ENGLISH HORTICULTURE.

It not unfrequently happens that wholesale growers of fruit and vegetables in this country are reproached for their want of skill and enterprise in allowing large importations of foreign fruits to undersell them in their own markets. Something may surely be said in their behalf. Englishmen are not generally wanting in energy, and in all callings there are to be found some persons possessing more than average intelligence, who are capable of looking all round a question and seizing on the points that are likely to tell in their favour.

On conversing some few years ago with one such person, who had an apparently flourishing business as a grower and greengrocer in a large town, he told me that he would not do his son the injustice of bringing him up to so unremunerative a business as his own. I may add that he rented many acres of good fruit and vegetable land just outside his town, with an ample command of manure, and ready access to London and midland markets for his surplus produce. The gist of his argument was obvious. However good the land, and whatever the skill in cultivation, there is nothing but uncertainty as to the result. A season of frost, of drought, of deluge, of blight, or general unfruitfulness (and something of the sort occurs more or less for four years out of five) reduces the condition of many horticulturists to one of incessant doubt whether or not they will be able to pay their way. To an amateur this uncertainty is of comparatively little importance. He plants more fruit trees than he ought to require, and

the same with vegetables; and so, as well as by the aid of glass, he can generally have his table amply supplied. To the market grower, however, even if there may be some exaggeration of the hardship detailed in the case of the one to whom I have just referred, there is no doubt that the character of the season means anything between either poverty or a moderate competence.

The result of fruit-growing in the southernmost portion of Surrey, to go no further back than the last three seasons, will illustrate what has been said. In 1879 tree fruits and many vegetables were a complete failure. There was a sunless summer of incessant rain and of slugs. 1880 was a generally unfruitful year (except in the case of Strawberries and bush fruit), for the wood had not ripened in the previous year, and of such fruit as did promise to come to perfection the plague of wasps devoured or destroyed a large portion. What shall be said of 1881? Perhaps it is too early yet to prophesy. Those who quote the hackneyed, but often baseless, sayings in vogue exclaimed in spring, "We shall have a good fruit year, for the winter has been long and cold, the spring late, and the wood is well ripened." Well, the beauty and profusion of blossom on all kinds of fruit trees this season have been such as can never be forgotten. It would go far to recompense an amateur grower to see his reward, not in the prospect of fruit, but in the rich display of floral beauty which what he may call his flowering shrubs have provided for him. We shall soon know how much fruit will follow this. On the night of April 21st there were many degrees of frost, and the blackened centres of the flowers of Pear trees told too surely that the hope of a full crop of Pears was at an end. Still, some of the later blossoms, especially on the more hardy sorts of trees, will secure, perhaps, a fair supply of fruit. But the season has been one of long and severe drought, and Plums and Apples, especially the former, have, after being well set, fallen in considerable numbers, apparently from dryness of soil. This remark applies chiefly to bush and pyramid trees, for the large Apple trees in the fields and orchards seem still to be laden with fruit.

Again, in this neighbourhood at least, the profusion of caterpillars is as remarkable as the profusion of blossoms. They have invaded all trees alike. On the Gooseberry and Currant bushes we have dealt with them effectually by hand-picking; but on many of the larger trees, where they run riot, they have so riddled and consumed the leaves, that if the trees should recover it will show how extraordinary an amount of mutilation a fruit tree will endure and yet survive. Much of the fruit, too, is scarred and disfigured from the same cause. Even the Oak trees are similarly attacked; half the foliage of some of them is gone. The ground beneath the trees is thickly covered with the black droppings of the little creatures, whilst the combined noises of their tiny jaws, I presume (a sound familiar to all who have kept silkworms), resembles that of a gentle fall of rain—gladdening the ear with the semblance, if not with the reality, of the showers for which we are all longing.

If I have not wearied my readers with unwelcome tidings I would say one word on the prospect of wasps. The long dry spring is the prime condition for an ample visitation of these creatures. Numerous queens appeared early. A day has seldom passed on which we have not slain many such, and we have rewarded children with a shilling a dozen for all they have brought us, but they are still numerous.

But is there not one remedy at least for much of the uncertainty attending the culture of the better kinds of fruit in this country? The late Mr. Rivers especially, genial and enthusiastic as well as practical in all that he wrote, a man with a mind so open and unfettered that he would welcome a promising suggestion even from the youngest hand in his employ, was, as is well known, a persistent advocate of the protection afforded to fruit trees of the better kinds by orchard houses or glass sheds. Cannot such structures, unheated artificially, be erected so inexpensively as to be available for the purposes of those who cultivate fruit as a means of livelihood? The trees in such a case, if not in all cases, being planted in the earth and not in pots, would save much trouble in incessant watering, top-dressing, and renewal of soil.

My own experience, if I may venture to adduce that of an amateur, during several years has taught me that I can rely with confidence on a good crop within the orchard house, however unpromising the prospect may be without. As I was permitted to remark in this *Journal* on a former occasion, and in a bad season, a thin film of glass alone stood between fruitfulness on the one side and comparative barrenness on the other. Is not this subject worth ventilating in the columns of the *Journal of Horticulture* by the skilled professional horticulturists who habitually enrich its pages?—A SURREY PHYSICIAN.

VINES DYING.—A singular misfortune has happened to three of

my Vines; one Black Alicante, two Madresfield Courts. I had a stage in the cool house to put plants on during winter. The ashes on the stage touched the Vine stems an inch thick. After starting and showing fruit they languished, and on examination we found they were growing strongly below the platform. It was at once removed. The young shoots are now growing well. The old rods are dead above the part where the ashes touched them. This is a severe lesson. The roots are outside; the rods within the house, just under the surface of the border. Other Vines in the same house are doing well, but there was no platform or ashes near them. The platform is 18 inches above the floor.—H. T. H.

#### POTATOES AND FROST IN JUNE.

As an illustration of our capricious climate the following notes may interest some of the readers of the Journal:—The temperature on several days for the week ending June 4th exceeded 70° in the shade. On one occasion, at 10.30 in the morning, I put a thermometer outside full in the sun, and in half an hour 120° Fahr. was indicated, 72° in the shade, while the week just ended (11th inst.) reminded us of dark days in October. It commenced with hail showers, and a minimum temperature within a few degrees of the freezing point was registered on the 7th, 8th, and 9th. On looking through some experimental varieties of Potatoes yesterday I noted the following—Myatt's Ashleaf, planted in October last, had all the young leaves blackened. Early Rose was not quite so much injured. Snowflake seems more tender than those named both in top and tuber, for some of them planted in October as an experiment, though covered with fine hay during winter, rotted. Flounder bore this low temperature better than any named. Fortyfold and Magnum Bonum perceptibly affected only; while Champion, planted last and making vigorous growth, is quite unaffected. As showing the advantage of a western aspect, on which the sun does not shine until eleven o'clock in the morning, Beauty of Hebron and Bresee's Peerless, though notably not so hardy, were quite unscathed.—W. J. M., *Clonmel*.

#### POINSETTIAS, THEIR PROPAGATION AND CULTURE.

AMONGST plants which bloom in November, December, and January, few are of easier culture and none more showy than Poinsettias. They are attractive at a time when flowers are highly prized, and their cheerful colour is highly pleasing. Now is the time to attend to their culture, and the best plants are secured when a fresh stock is rooted annually.

Assuming that the plants which flowered last year have been preserved, if placed in a heat of 60° they soon produce young growths all up the stems. It is these shoots when from 2 inches to 4 inches in length which make the best cuttings and the best plants. As they are very succulent it is a bad plan to use the knife to cut them, it being much better to break them off with a heel—i.e., a small piece of old wood attached to the base of each shoot.

Sand and leaf soil are the only two ingredients which need be used in the compost, and the pots should be of the smallest size, or what are known as thumbs. Into each of these two cuttings may be placed, but not in the centre, as they root much better near the edge. They strike quickly in a bottom heat of 80° to 90°, but should be withdrawn from this as soon as the roots are well formed, and after a week or more they may be transferred to 4-inch or 5-inch pots. These must be very carefully drained, and soil of a more substantial kind must be used now. This should be composed of loam, half-decayed manure, and a good quantity of sand in suitable proportions.

In potting the young roots must not be broken, but the soil may be pressed firmly round them, and care must be taken that a check is not given immediately afterwards. To avoid this the plants should be placed in a close warm frame or house, and it may be necessary to shade them from bright sunshine for a few days; but this should not be continued longer than is wanted, as they bear exposure to sun well when growing. A cucumber pit is very suitable for Poinsettias in summer, and we have seen good plants grown in cold frames, where they become dwarf. For some purposes tall plants may be required, but as a rule dwarf plants are in the greatest request. Useful plants may be had in 4-inch and 5-inch pots, and larger pots may not be needed, but if they are the plants should be shifted before becoming rootbound. As it is the point of the shoot which produces the head of bracts, care must be taken to keep this part uninjured. From a plant with one shoot only one head of bloom can be had, but if this can be obtained a foot or more in diameter it will be more ornamental than another plant with two or three puny heads.

From the time the plants become thoroughly established in the

pots until well into the autumn they must have liberal supplies of water, and liquid manure may be given once a week. Strong healthy plants are not very liable to insect attacks, but should such occur careful spongings must be at once resorted to. No shading must be employed after the plants are established, as plenty of sun heat matures the wood and conduces to early and fine heads.

As soon as the nights become long and chilly the plants should be removed to warmer quarters, and to produce bloom they must be placed in a temperature of about 60°. At this time they should have abundance of liquid manure and a light position. Although a temperature of 60° may be required to cause the bracts to develop freely, they do not need so much heat as this when fully expanded, as then they stand well for a long time in a warm conservatory. By placing them in heat as required a long succession of heads will be the result; and the plants must not be suddenly starved into rest, or stock may be scarce when wanted in the propagating season again.

Of varieties hardly anything need be said. The old variety now so well known is still the most useful for general culture.—M. M.

#### JOTTINGS BY THE WAY.

ON my usual visit to the great Whitsuntide Show at Manchester I determined to go somewhat out of the beaten track. I had a desire to visit St. Albans to see what was being done with the grand old abbey, or Cathedral as it will now be called, and to have a look at an establishment which has come into prominence during the past few years—that of Messrs. F. Sander & Co. In common with many others I must deplore what is being done at the abbey. Sir Edmund Beckett has given largely to it, but at what a cost! He has taken away the old western end, and is putting up one of his own design. I do not pretend to be an architect, but I am conservative, and have a notion that they knew better how to build in those days than we do now. At any rate I am not alone, for I met one who evidently was an architect, and he was in a white heat, threatening to bring the matter before the Houses of Parliament.

The establishment of Messrs. Sander is, I should think, perfectly unique. I have seen, of course, the grand establishments of Messrs. Veitch and Bull with their beautifully arranged houses, where everything is in the perfection of order and neatness; and as Messrs. Sander devote themselves almost exclusively to the same work I looked for something of the same sort, but nothing of the kind, as Mr. Sander said, "We do not grow Orchids; we simply import. Our collectors send home plants to us from all parts of the world, and we sell as soon as we can." You enter from the street through one of those country seedshops with which we all are familiar, and you find yourself at once in the midst of a conglomeration of glazed sheds, low, dark, and untidy. You step probably into a hole which sends the mud over your ankles, or you knock your hat against some low patched roof which obstructs your way, and yet amidst all this there is a wealth of Orchids there which is something remarkable. What a sensation when the first plant of Anthurium Andreanum was exhibited at South Kensington! and how fiercely waged the battle as to who had the real one! A controversy, however, soon set at rest that there was but one variety; and here lying on the shelf of a low-pitched house were hundreds of its curious fleshy-looking roots, reminding one more of a parcel of newly born ferrets than anything else I could think of, and besides quantities of seedling plants, so that ere long it must be within everybody's reach. Then here were houses full of Cattleyas, others of Odontoglossums, and again of Masdevallias—all imported plants, many of them in the daintiest little pans all ready for being sent off. Houses were being added to, and everything indicated a very prosperous business; yet it has only existed for twelve years and is carried out with Teutonic energy, for Mr. Sander is one of those citizens of the Fatherland for whom Prince Bismarck has been so pathetically pleading of late that they are elbowed out in the southern seas by Englishmen; whereas the reverse of this seems to be the case. They are the Scotch of the Continent; and as it was once said, If you get to the North Pole it would be ten to one that you would find a store there and Sandy McAlister trying to do a stroke of business with the Esquimaux and polar bears; so everywhere Germans are to be met with keen, frugal, and quick-witted to seize an opening and to keep it to themselves when once they have it.

When I reached Warrington I paid a visit to another small establishment, quite as remarkable in its way, although in this case belonging to an amateur. Mr. W. Bolton is an Auricula and Polyanthus grower and his Auriculas are grown at the back of his house in the town surrounded on all sides by factories and

houses and by a sweet combination of smells which even Cologne could not excel, and yet they were in excellent, nay, vigorous health. The house in which they are grown is not an imposing one, but it is airy. It is not kept in the neatest order, but the plants are sound. The minute directions by which we are told how to manage Auriculas are despised. The soil used is no pasture loam, but common garden soil. The pots are mostly glazed; but as the proof of the pudding is in the eating, so here is a proof that the Auricula is much more accommodating than we are in the habit of giving it credit for. The collection here is nearly a complete one. All the best sorts are represented, not merely the older varieties, but such varieties as Simonite's Frank Simonite and Ben Simonite, Horner's Ringdove, Reed's Aeme, &c. Mr. Bolton was a successful competitor in the classes for Polyanthus at the Show at South Kensington, but does not think very highly of the taste of the south. He says the Loxford Hall collection is one of the largest he knows, but, like most northern growers, thinks the plants are grown too coarsely in the south, too much forced, the sticks being an innovation no northerner can look with any favour upon. Has he the woolly aphid? Yes, certainly, everyone has; but then my experience and that of others has been an advantage to other growers. They look for it and kill it as soon as it appears. It is still, as ever, a mystery. America has now got the credit of it; and up here they say it was imported with some Primulas from the same country to which we owe the American Apple blight, the Colorado beetle, and, some will have it, the phylloxera. Now here is one instance of what the north does in the way of florists' flowers. You may search the whole south of England and you will not find a case like this, and yet through all the large towns of the north such growers are to be met with—enthusiastic, devoted, and intelligent; and it is because we have not this element as we used to have in the south that the revival of a taste for florists' flowers seems so hopeless.

At Grappenhall, where my journey ended, I had an opportunity of seeing how Roses were looking in the north; and if my friend Mr. Tinsley's are an indication of their general condition all certainly looks well for a good Rose year. Some of the recently planted Roses looked seedy, but his own cut-backs, which had all been replanted in the autumn, looked admirably. The buds were showing well, and as there has been more rain here than with us the plants were full of fine foliage; and the copious rain we have had during this Whitsuntide, while it has sadly interfered with the pleasures of our holiday-seekers, has greatly helped on our Roses. I had also an opportunity of talking with my friend Mr. Hall of Rock Ferry, who gives the same favourable account of his plants. I have seen some in the south which look well, so that I think we may reasonably hope for a good Rose year.—D., Deal.

[Since the above was written Mr. Tinsley's Roses have unfortunately been much injured.]

#### DOUBLE FLOWERS.

I HAVE been expecting to see some notice taken of the poetical article of "SINGLE-HANDED" on "Double Flowers," but it seems to have awakened few responses amongst your readers. It would be useless to try to prove to your talented contributor that a double flower may be as beautiful as a single one, and in some cases more so, as for example in that of the double forms of *Ranunculus bulbosus*, *Achillea Ptarmica*, and *Cardamine pratensis*. It would be equally useless to discuss the question whether we ought to grow improved forms of flowers or not—say, for instance, the improved form of Pansies in place of the weed *Viola tricolor*, or the large and varied forms of Chinese Primroses instead of reverting to the poor forms common fifteen to twenty years ago. I quite agree with him respecting the beauty of wild flowers; indeed, I was on my way to gather bunches of wild Tulips and the wood Forget-me-not when the Journal came to hand containing the article in question. These and other denizens of the woods, which are sent to London are perhaps as much valued as Orchids. I also quite agree with him as to the beauty of the Buttercups, though I believe the plant he refers to is Marsh Marigold, and known amongst botanists as *Caltha palustris*. We have a beautiful double form of it growing in the borders, although our soil is a dry one. The wild Hyacinths will grow anywhere without trouble; and when about it I would strongly advise your correspondent to add many more weeds to his wood garden than he has named. Besides those named here, the Woodruff, the Leopardsbane, Monkshood, Primroses, Wood Violets, Wood Shamrock, Lythrum Salicaria, Geranium pratense, and *G. sanguineum* (in open places), Snapdragons, London Pride and other Saxifragas, Campanula latifolia, Lily of the Valley, Orchis mascula and *O. maculata*, Spiraea Ulmaria, Sweet Rockets, and doubtless many other wild flowers

are all suitable for naturalising. I would strongly advise "SINGLE-HANDED" to keep the hoe from them, as I cannot think a carpeting of green grass for such flowers would be in bad keeping.—R. P. BROTHERSTON.

#### FLORAL EXHIBITION AT THE ALEXANDRA PALACE.

THE second of the competitions with table decorations, bouquets, buttonholes, and other methods of floral adornment, was held on Friday and Saturday last, Pelargoniums also being provided for in several classes, and occupying the same position as the Roses at the previous Show. The former portion of the display was very attractive, the competitors numerous, and the general quality satisfactory. The Pelargoniums imparted considerable brightness to the Exhibition, the arrangements as usual being judiciously superintended by Mr. J. Forsyth Johnson.

Dinner tables were well represented, fourteen being staged in the two classes devoted to them. The best table set for twelve persons was arranged by Miss A. Williams, Victoria Nurseries, Upper Holloway, who was adjudged the first prize in a competition of six for a neat and tasteful arrangement. The central vase contained in the upper portion Grasses and Rhodanthes, the base being occupied with Anthuriums, Gloxinias, Pelargoniums, Orchids, Roses, Lilies, and a groundwork of fronds of *Osmunda regalis* and *Adiantum cuneatum*. The side designs each consisted of a plant of *Cocos Weddelliana* in the centre, surrounded by flowers of *Ixoras* and Lilies. The fruits represented were Cherries, Strawberries, Oranges, and Grapes. The second position was accorded to Messrs. Dick Radclyffe & Co., High Holborn, who had a light and pleasing design. Mr. J. R. Chard, Clapham Common, was a good third. Miss A. Williams was again the most successful exhibitor of a table set for six persons, and carried off the chief prize with an elegant yet simply decorated table that was greatly admired. The centre stand was a trumpet-shaped glass vase, bearing in the upper portion flowers of *Centaurea Cyanus*, Rhodanthes, and various Grasses; while the base contained a diversity of Orchids, with Anthuriums, Spiræas, Caladium leaves, and *Adiantum* fronds. No fruit was employed, and this was objected to by some of the other exhibitors, but the table was clearly the best shown. Mr. W. L. Buster, St. Mary's Cray, Kent, and Mr. W. Brown, St. Mary's Grove Nursery, Twickenham, followed in that order, the last-named having a pretty arrangement but containing rather too many yellow flowers, though some handsome Allamandas were very attractive. The competition with hand-baskets of flowers was spirited and interesting, there being no less than eight entries. Miss Williams was first with a charming contribution, comprising flowers of *Chrysanthemum Etoile d'Or*, Spiræas, Dendrobiums, especially *D. tortile*, and Fuchsias, with foliage of *Lonicera aurea reticulata*, Caladium argyrites, and various Ferns. Mrs. A. M. Stuart, 84, Seven Sisters Road, was second with a tasteful collection of Ericas, Masdevallias, Oncidiums, and Rhodanthes; Miss Cluse, Woodford Bridge, being third with a rather heavy design.

Seven brides' bouquets were staged, that very successful exhibitor, Miss Williams, taking the lead with a combination of *Phalenopsis grandiflora*, Gardenias, Stephanotis, *Dracophyllum gracile*, and Rose buds, but with a rather too free intermixture of Fern fronds. Mr. F. J. Taylor and Messrs. Jones & Son, Shrewsbury, secured the other prizes in the order mentioned. Bridesmaids' bouquets were well shown by Mr. Brown and Mrs. Stuart, who were adjudged the first and second prizes respectively. Ballroom bouquets were very bright, but not numerous. Miss Williams had the best three; one containing flowers of *Franciscea calycina*, *Ixoras*, Oncidiums, Roses, Ericas, and Stephanotis was especially tasteful. Mr. Brown was a close second with satisfactory contributions. Flower stands for a drawing-room table were exhibited by Mrs. Stuart, Miss Baines, Palmers Green, and Miss Cluse, who were accorded the prizes in that order for bright and pretty combinations of flowers. For six buttonholes Miss Baines secured the premier award with neat arrangements, in which scarlet and white *Bouvardias*, Rose buds, *Hoya bella*, and Forget-me-nots predominated. Mrs. Stuart was second with neat combinations of Orchids, chiefly Masdevallias; and Miss Williams was a close third.

Pelargoniums were contributed by Mr. Wiggins, gardener to H. Little, Esq., Uxbridge; Mr. G. Osborne, gardener to J. N. Mappin, Esq., Southgate House; and Mr. C. Hammond, gardener to F. Hurst, Esq., York Lodge, Stamford Hill, all staging well-grown specimens, and obtaining the prizes in the above order. Mr. Little's plants were similar to those which gained the chief honours at the South Kensington Show.

The next Exhibition is to be devoted to Cherries and Strawberries, and is announced for the 1st and 2nd of July instead of the 17th and 18th of the present month. It is likely to be very interesting, and there is promise of good competition.

#### PRITCHARDIA GRANDIS.

EARLY in the present year we noted that importations of this handsome Palm had been received in England, and that young plants were being distributed by several nurserymen. We now present our readers with an illustration that well indicates the chief distinguishing characters of the species. A few years ago this Palm was only represented by two specimens from the South

Sea Islands, one of which died, and the other passed into the possession of Mr. Wills, and has since been one of the attractions in the Anerley Nursery, where it recently produced flowers but failed to perfect seeds. The young plants now in this country were, we understand, originally sent to Kew, whence they have been distributed.

All the species of *Pritchardia* are noble Palms, *P. pacifica* and *P. filifera* being well known and admired; but *P. grandis* is, perhaps, unrivalled in its majesty of habit. The orbicular leaves sometimes attain a diameter of 2 feet. It appears to require a stove temperature to obtain it in satisfactory condition, but is reputed to be of easy culture, and no doubt when the plants become more plentiful and more generally known it will rank among

the finest Palms in cultivation. The accompanying figure, for which we are indebted to Messrs. Veitch, is a truthful representation of this fine Palm in a small state.

#### AN AMATEUR'S FAVOURITES.

My object in writing these notes is simply to show how amateurs who, like myself, possess a greenhouse, can keep it gay during almost every week in the year at a comparatively trifling expense. My greenhouse is entirely unheated, and yet I have so far succeeded in keeping up a satisfactory show from the middle of February to the last week in December. I find January the most difficult month to deal with, and should feel obliged if some

Fig. 108.—PRITCHARDIA GRANDIS.

correspondent would be kind enough to inform me, and others in my position, what plants can be had in bloom without any heat during this dull month. It strikes me that amateurs as a rule try to grow too many plants: to this cause I think may be ascribed many failures. The only plants I grow in quantity are Chinese Primulas, Cinerarias, Calceolarias, Pelargoniums, Balsams, Achimenes, Tuberous Begonias, and Chrysanthemums, which are here named in their order of blooming.

Perhaps I may be allowed to give a brief summary of my operations. The Primula seed is sown either in May or June; after the young plants obtained have been potted singly, they remain in a cold frame till early in November, and come into bloom early in February in an ordinary season. The Cinerarias are also grown from seed, which is sown about the 10th of July, the Calceolaria seed being sown three weeks later. Zonal Pelargoniums are the most necessary plants in a greenhouse; cuttings being

inserted in 48-sized pots at the end of June, three in each pot, they are fit for separate pots in September, and may remain out of doors until November, provided there is no frost. The Pelargoniums are at their best in June; in July I place them outside, and they yield a fresh supply of flowers for at least three months. The mode of culture for Balsams described in a recent number of the Journal I entirely agree with. Last year my plants flowered in 24-size pots, but intend to give them larger pots this season. Achimenes are great favourites with me. If small plants are obtained about this time, and placed in light rich soil and not overpotted, they will flower through August and September, but they must have the sunniest place in the house, and be watered rather sparingly; liquid manure applied in a weak state will prolong their blooming season to a great extent.

I grew Tuberous Begonias last year for the first time. They had not, it would appear, been seen in the neighbourhood before, and

many visitors were simply enraptured with them, one lady vowing that she would pay my greenhouse a nocturnal visit with the object of abstracting some of the "beauties." Seedlings may be bought cheaply in May and June and make a fine display, but of course cannot be depended upon for variety the same as the named kinds. Some of the scarlets and crimsons are certainly magnificent; and readers of the Journal will perhaps be amused to hear that, wishing to increase my stock of named varieties, I proceeded early in April to cut up the tubers as if they had been so many Potatoes. To my great delight my collection had suddenly quadrupled. But great was my disappointment, some three weeks later, on inspecting the tubers, or rather the pieces, in the pots to which they had been transferred, to find that they were all decayed. This is a lesson not easily forgotten, and, *malgré moi*, I was forced to send to Messrs. John Laing & Co. for a fresh stock. I flower my Begonias in 32-sized pots, unless they are extra-large plants, in which case they receive another shift. They can be depended upon to bloom from August to the end of October without heat. Of course they would bloom early in the summer in a warm house.

**Chrysanthemums.**—Small cuttings are inserted in large 60's, three in each pot, as soon as the blooming season is over, the old plants being then thrown away. Early in May they are transferred separately into 32-size pots, and about the end of June receive their final shift into 16's, which size I find the most useful for the Chrysanthemum.

All the above plants I have found to give the least trouble and the greatest satisfaction. My chief difficulty arises with the Calceolarias, as the leaves shrivel up without the least notice just as the plants are about to bloom, and there is no apparent reason for their dying in this way. I may add that if a few Camellias are desired they will make charming companions for the Primulas, whilst Azaleas will add to the fine colouring of the Cinerarias, and half a dozen selected Fuchsias may lend an additional charm to the house when the Pelargoniums are on the wane and the Balsams are not yet in full beauty.—P. C., Jersey.

#### WHAT PLANTS USE.

(Continued from page 468.)

VINES and all other plants use carbon dioxide. They do more—they use up heat and light. It is not very easy sometimes to get people to understand this; at least we have as often been rewarded by a shaking of the head in a manner indicating unbelief when we have verbally tried to explain that they did so. We hope we shall have more success with our pen. This is not the place to enter into a philosophical explanation of what heat and light are, but the following may help those who have given the matter no thought to understand that plants use up light and heat. Burn a piece of wood: while burning, heat and light are given out. Is this heat and light a new production? Many persons regard it as so, but it is not. Both were stored up by the leaves of the growing tree. While water and carbonic acid gas are being decomposed in daylight, as surely as these are manufactured into new form and stored up, so surely are light and heat stored up; and when by the process of combustion these forms are again resolved into water and carbon dioxide, again the light and heat, which were latent in the wood, assume their original form. More than that: according to the rapidity of the combustion so is the evolution of light and heat, and in proportion of the amount of light to the heat in our plant houses is the opposite operation—the composing of hydro-carbon performed. Without heat the process cannot go on; without light the process cannot go on; and without water and carbon the process cannot go on. All these must be present at once to secure the building-up of tissue. The attempt to secure it with any two only will not do. Heat and light together without air may forward plants towards the maturing of their wood, fruit, or foliage; but new material cannot be formed under such conditions. Heat and air alone are not sufficient to do it in the absence of light; and light and air alone are not enough—heat must also be present, and only the last seems to be generally understood.

Bearing these facts in mind, where is the economy of shutting up heat which can never be used? In daylight it is, in one sense, useless without the air; during darkness it is useless without the light. It is only useful in producing precocity at the expense of the quantity and quality of the fruit, for it does tend to the weakening of the Vines. And instead of burning coal to keep up a hurtful heat during the hours of darkness, would it not be far better to maintain the heat during daylight with it, and then keep up the heat with ventilation to the same extent as is usually done without? We think so, and we act so, and are satis-

fied that we are right—right in the way we have read the lessons science has taught us, and right in our practice.

But circumstances compel us to make compromises. With a bright February sun, a house full of tender foliage, and an outside atmosphere a number of degrees below freezing point and in rapid motion, the opening of ventilators would speedily work ruin. We have sometimes, under these circumstances, aired an early house by opening the door into the next compartment and ventilating it freely. Sometimes there is no adjoining vinery. In that case we have opened the front ventilators a little and tacked a strip of scrim over the opening; the air passed slowly through this and escaped all over the roof through open laps. In the case of houses with puttied laps—a bad practice—we have opened the top ones a little and put scrim over them too. We have done this also in the case of Melon and Cucumber pits and have found the practice good.

Ventilating, even in winter, might be a simpler and a safer operation were our hothouse builders better up to their business. Very few houses are so ventilated that the air is warmed before it can circulate among the plants with safety. No better plan has been invented than that by Mr. William Thomson, Tweed Vineyards. "It is termed the hot-air ventilator, and consists of a sheath of copper placed over or encasing a row of the front pipes. The diameter of the sheath is 1 inch more than the hot pipe it encloses, consequently there is an open space all round the pipe inside the sheath. This cavity is fed with fresh air from the exterior of the house by a pipe 5 inches in diameter, which springs from the lower surface of the sheath and passes through the front wall of the house to the external air. There is a valve in this feed pipe to modify the supply of fresh air at pleasure. In the upper surface of the sheath is a double row of holes, so that the moment the cold air comes into the chamber round the pipe and gets hot, expanded, and lighter, it makes its exit through these holes into the general atmosphere of the house." We quote from "Fruit Culture Under Glass," by D. Thomson. Another efficient simple "hot-air ventilator," which may be seen at Brentham Park, Stirling, consists of a cast-iron pipe full of holes laid under the hot-water pipes and communicating with the outer air through the ends of the house. This has also a valve to regulate the air. Ordinary ventilators are all right in summer time, but in winter some such ventilators as the above should be in use in every house where genial temperatures are kept up. Indeed they are the best even in summer, for by their use cold draughts may be avoided.

We have spoken hitherto of the admission of air to vineries and such structures. The principles we have endeavoured to lay down apply in all cases. All plants, however, do not demand the quantities of carbon which strong-growing Vines do. The amount of carbon assimilated by a growing Orchid is trifling comparatively speaking; and if we take into consideration the amount of carbon dioxide that must be continually escaping from decaying sphagnum, &c., the little air that is necessary to keep the air sweet, that which is always entering when doors are opened and through the laps in the glass and otherwise, there can be no doubt that, generally speaking, such plants do not require a change of air to anything like the extent of plants which consume carbon rapidly. Even stoves require little air, in winter at least, for then the plants require little. In summer it is somewhat different, especially when houses are crowded with quick-growing plants, and the roof is covered with Allamandas, Passifloras, &c. Greenhouses require to be ventilated whenever the sun is out to keep down the temperature all the year round, and in dull weather during winter to keep away damp, so that these are generally ventilated efficiently. It is where high temperatures are necessary and when houses are crowded with foliage, that most mistakes are made.

We intended to say more on the use plants make of water in this paper, but it is already long enough, so we will leave that over for another issue of the *Journal of Horticulture*.—SINGLE-HANDED.

#### DOUBLE FLOWERS—BEDDING PELARGONIUMS.

I HAVE been rather amused at the attack made by "SINGLE-HANDED" on double flowers, and thought someone would take up the cudgels, which I see "Y. B. A. Z." has done in the matter of Roses. I have a theory that single flowers bear doubling better than those that have trusses—for instance, double Pelargoniums are not so fine as single, nor would a flower like a Verbena or Phlox Drummondii, or any of the suffruticosa section, be improved by doubling, though this rule will have its exceptions, as with the double pink May, and it seems that the double flowers last longer than the single.

Has that beautiful single Dahlia, the Dahlia imperialis, which

bloomed so well at Cannes in the autumn, ever been tried out of doors in the south of England?

I have finished all bedding-out. The Geraniums were very forward in bloom, as there was so much sun in May. Pearson's strain of Pelargoniums still seem to me to take the lead. Mrs. Leavers and Lady Emily among the pinks; A. F. Barron and The Shah amongst the crimsons and scarlets; also those very good old sorts the Rev. F. Atkinson, John Gibbons, and Charles Smith. Henry Jacoby, which was recommended by one of your correspondents, will, I fear, burn in the sun, but it is a very dark shade of crimson where sufficiently shaded.

I send you rather a curiosity. I had picked some variegated tricolor leaves from Sophia Dumaresque, and they were placed in water on my writing table, and to my surprise began to root in the water. From mere curiosity I left them there, and though the leaves are withering yet the roots are still fresh. I have hardly changed the water. I am going to pot one to see whether it will push up an eye from the base, as they were merely leaves pulled off from cuttings.—C. P. P.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 24. NEW SERIES.

THERE is another spinning mite, nearly allied to the red spider, that has been described by Boisduval, who found it frequenting the Vine; and it probably occurs sometimes in Britain, though observations made upon it here, if any, have not been recorded in print. This mite, called *Tetranychus vitis*, is hardly half the size of the red spider, and of a yellowish hue. It occurs in little colonies, which spin a number of loose threads upon the leaves of the Vine, quite different to the closely woven web of silk under which the red spider carries on its destructive proceedings. The effect of the presence of *T. vitis* is first the discoloration, then the withering of the leaves; but as it only shows itself upon the Vine towards the end of the season, Boisduval thinks at present there is nothing to be apprehended from it—at least in France, the yield of Grapes not being diminished thereby nor the Vines themselves injured. So good a report cannot be given of the next species I mention—*T. tiliarum*, another minute insect of an orange yellow, and which has at times been found in such swarms upon the leaves of the Lime in some parts of the Continent as to give to the trees, viewed a short distance off, an unhealthy yellow tint, displacing their natural green colour. The injury they do is, as in the rest of the fraternity, attributable to a sucking apparatus, for mites do not nibble the leaves. During some seasons this species has also occurred abundantly upon a variety of plants in the kitchen garden, French Beans and Cucumbers, for instance, to their injury. Fortunately it does not yet come nearer to us than France, though we shall be always liable to have these and other small pests transferred to our shores.

We proceed to another spinning mite, too well known because painfully known to many inhabitants of Britain. Its history, however, has only been made out recently, and its position as a mite decided to be amongst the spinning mites in the genus *Tetranychus*. This is popularly called the harvest bug. The scientific name, *T. autumnalis*, also points to the season of the year when it is generally noticed. As to localities, it appears to be particularly fond of chalky districts and of the coast. Less than the red spider, it nearly resembles it in colour, and from its minuteness it is scarcely perceptible upon any object unless the eye happens to fall upon it in the act of moving. Placed under a magnifier the body is seen to be covered with bristles, and upon the head are two sharp points above the hollow snout. The notable peculiarity of this species is, that although the mite commonly occurs upon vegetable substances, doubtless therefore subsists upon them during its period of growth, it migrates to the skin of animals when it has a chance of so doing. Reputed to haunt cornfields, where it is frequently found, the harvest bug is also common in meadows and amongst Turnips; nor is it excluded from gardens, where persons have in various instances suffered from its attacks after they have been engaged in picking Gooseberries and Raspberries. Where individuals are infested by it, the restlessness and irritation in some cases will cause feverish symptoms. As happens with similar insects, there are certain persons upon whom the harvest bug will not crawl, perhaps because the skin is distasteful from its giving forth some peculiar smell; and it has been stated that small doses of sulphur taken regularly have such an effect upon the skin as to lead the harvest bugs to shun those who may have tried this plan of keeping them off. The remedy being both safe and simple, it may be recommended to those who are liable to be teased by the species. Possibly it might be useful in preventing the approach of other annoying insects. *T. autumnalis* has this peculiarity attaching to its proceedings, that it manages to insinu-

ate itself under the skin, when the result of the mite's burrowing is shown by the appearance of a small pustule. In performing this feat it is assisted by the prominences upon the head to which allusion has been made.

The harvest mites proper have only been partially studied, like many others in this obscure division, and some species that have been named—*Trombidium parasiticum*, for example, are perhaps only the larval stage of species previously recognised. This is a very small six-footed mite, brilliant red in colour, which has been taken upon the wings of the house fly both in England and in America, weakening if not positively killing the larger insect. Various species beside this in the above genus are parasitic, therefore probably rather to be deemed useful than injurious. Curious differences of habit are noticeable in some, depending upon their stage of growth or the locality they haunt; thus *T. holosericeum*, while yet a larva, has been taken upon the legs of spiders. When older and stronger this mite has been observed to feed upon aphides; and if Mr. Stewart is right in his belief that it seizes newly-hatched caterpillars and sucks them dry, the species may be welcomed in gardens. This mite does not spin, hence it is thus distinguishable from the red spider, which it resembles in colour; also it is larger, the body is silky, legs six in the larva, and eight in the fully developed mite. The worthy and indefatigable entomologist De Geer has mentioned a species he calls *T. aphidis*, which takes as its prey the familiar black aphid. This is perhaps the *T. aurantiacum* of recent naturalists, a thick-bodied orange-coloured mite, about which we have only "foreign intelligence" now, though the species may be British. It is to warmer countries than our own—to Africa for instance—that we should have to go if we wished to see mites in their bulky forms, and where we might find them as large, or larger, than a full-sized ladybird. Leaving the water mites and sundry species besides that are related to the preceding, I notice one of the snouted mites, since it has received an honorary mention from Curtis in his "Farm Insects." This is called *Scirus insectorum* by Hermann; it had before been incorrectly named *Leptus phalangæ*, when only the larval form had been discovered. Curtis considers that it checks the increase of the wireworm by its attacks upon the beetle producing that. But it has been taken not only upon beetles, such as the Elaters; it has also been seen adhering to the limbs of the long-legged crane flies. This rather exceeds the *Trombidii* in size; it is reddish in colour, somewhat "scraggy" in figure when young, but plump when adult, furnished with a peculiar snout. The Gamasids are mites parasitic on various animals, several upon beetles. *Uropoda vegetans* is one of these, remarkable for having a cord by which it fixes itself upon the insect, usually upon the under side, where these mites are often found by scores, or even by hundreds, so densely crowded that individuals are placed above each other, though all deriving their nourishment from the beetle infested, which probably succumbs to the attack sooner or later. The body of *U. vegetans* is buckler-like and shining brown. As in the whole group of the Gamasids, the eyes are absent. Some of these mites have been detected upon vegetable substances, seemingly waiting for an opportunity of fixing themselves upon insects that might approach the leaves or flowers. In the genus *Dermanyssus* are soft-skinned mites, parasites on warm-blooded animals, as in the very common *D. avium*, popularly designated the "tick," though not a true tick, and which annoys poultry and cage birds. From the transparency of the skin these mites are seen to change colour as the blood they have taken in undergoes the digestive process. Scrupulous cleanliness is essential.—J. R. S. C.

#### NOTES FROM TASMANIA.

HAVING noticed several communications in your valued Journal commenting upon vegetable produce and the demand and supply existing in London and some of the large towns, I have thought that a few remarks upon kindred subjects might be of interest to some of your readers, though relating to the distant isle of Tasmania. Of course there is a vast difference between the demand and supply in this colony to that existing at home, inasmuch as we have only two towns of considerable size, and their population will appear small to English readers—Hobart Town, 22,000; Launceston, 11,000. But there is one difference in our favour, that the population, rich and poor, all know how to appreciate and use largely quantities of vegetables of all the varieties that are produced in this favourable climate.

"WILTSHIRE RECTOR'S" remarks as to the apathy of the English labouring classes in their use of vegetables is very noticeable when compared with the colonies; for, from the large quantity of vegetables consumed, it is apparent that it is not the result of other commodities being too dear, as bread and meat are both

much cheaper than at home, flour being £9 per ton, bread 5d. per 4 lb. loaf, beef and mutton from 2½d. to 5d. per lb. according to cut; so that it is very evident that a wide difference exists between the labouring classes of England and Tasmania.

"WILTSHIRE RECTOR" suggests that to further the greater use of vegetables, a daily visitation of all streets and alleys with carts and barrows should be made. Such a course would, I think, result in increased sales, as it has done here in the colonies; although not by carts and barrows only, but latterly more especially by the Chinamen, who with bamboo baskets carry Carrots, Parsnips, Potatoes, Beans, Peas, Cabbages, Cucumbers, Marrows, salading, &c., and fruit in season, daily tread through every street and corner, so that consumers have any vegetable they wish thus brought before them daily.

It is surprising the amount of patience and perseverance that "John" exhibits in carrying such heavy loads upon the bamboo day after day, often under a scorching hot sun. They start early in the morning upon their rounds, taking separate districts, and after serving their customers return to work in their gardens after their own peculiar fashion of multitudinous beds and alleys; all their beds being about 3 feet wide and flat on the top, and raised about 6 or 9 inches by the taking-out of the alley between, just allowing room enough to work between. Thus the ground after being worked is never trod upon, as all operations are carried on from the dividing alleys. They appear to be excellent judges of what to grow and how to grow it profitably, as they reject all crops that are a long time in coming to maturity, selecting principally small things, such as salading, Cucumbers, Vegetable Marrows, Kidney Beans, and Tomatoes, which they grow largely and well, preferring to buy the heavier vegetables off European growers. Although there is a great outcry in all the colonies against the Chinese as immigrants, yet they are patronised to a great extent in the sale of their vegetables.

Lannceston is said to possess the most abundant supply of water for domestic purposes of any town in the Australian colonies, which is brought into the town by iron pipes from the St. Patrick river, some twelve miles distant. The Municipal Council grant a supply of water for gardening purposes upon payment of special rates, which is an inestimable boon in this dry and, in summer, very hot climate. This year has been very trying to gardeners; the spring was late and very wet, with quite a plague of slugs, which made havoc amongst the Peas and Carrots especially, two and three sowings having to be made. After a wet spring hot and dry weather set in early in December, as on December 4th I planted out a large breadth of Cauliflower, Savoys, and Broccoli, and after this date until March 25th no rain fell in sufficient quantity to penetrate the soil to much advantage to the crops. English gardeners can form some idea of the effect of such a drought on tender crops under a burning sun, a cloudy day being very rare, and often high winds prevail, drying up everything. Under these circumstances a water tap is a great help, as without its aid not many tender crops would survive and be fit for market.

Tomatoes have during the present season been largely grown here, and have done remarkably well. Year by year the consumption of Tomatoes increases, and as this climate suits their growth the fruit forms a leading article of food during the season. The land is prepared for them as for Potatoes—by ploughing twice, harrowing fine, and planting 3 feet 6 inches apart each way, then keeping the land clean. This is all the attention they receive (no stakes, tying, stopping, &c.), and they continue to ripen up till the end of April, when they are cut by frost.

If of any interest to your readers I will endeavour to send you a few occasional notes from Tasmania.—F. WALKER.

[Such notes as you can send will be very welcome.]

THE action brought by Her Majesty's Commissioners of the Exhibition of 1851 against the ROYAL HORTICULTURAL SOCIETY and the debenture holders to recover possession of South Kensington Garden was yesterday morning decided in favour of the Society, and dismissed with costs, by Mr. Justice Fry, after an elaborate judgment, which we shall give *in extenso* next week.

— WE have received a plant of PAULINE STRAWBERRY from

Mr. George Paul of Cheshunt, bearing a heavy crop of fine ripe fruit. The plant has been dug from the ground, and in the absence of any communication to the contrary we presume has been grown without protection. The distinct earliness with the good size and quality of the peculiar elongated fruit now before us are particularly noteworthy. This Strawberry was figured and described on page 53 of our last volume.

— THE weather last week was of an extraordinary character, snow having fallen in northern districts; and a Lincolnshire correspondent informs us that "frosts on the night of the 7th and 8th inst. quite killed rows of Scarlet Runners, and blackened the growths of the Potatoes in many gardens." We are able to confirm this statement, as we travelled through the county this week and observed by the side of the railway similar results to those alluded to of frost in June.

— AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Major F. Mason in the chair, the following candidates were duly elected Fellows of the Society—viz., Capt. G. W. Archer, R.E.; Capt. O. Barwell, Lowther Bridger, George Frederick Butt, Gerald Carew, Octavius L. Ciare, John Collinson, W. L. Corey, Miss F. de Witte, John F. Vesey Fitz-Gerald, Mrs. Joseph Gibbs, Capt. J. C. Giffard, Capt. H. L. Hallewell, Viscount Hawarden, Sigmond Hoffmann, J. C. Humphreys, Henry James, Mrs. Kearsey, Wm. Ramsay L'Amy, D. P. Loc, Sir Moses Montefiore, Bart., E. D. Morgan, Mrs. Moul, Mrs. Murphy, J. D. Paul, Sir Ughtred Kay Shuttleworth, Bart., Colin W. Simson, George M. Smith, Lt.-Col. J. Stanley, Wm. Swinscow, Mrs. Arthur Tower, George T. V. Wills, and Henry Maitland Wilson. Mrs. Swinscow was elected a guinea Member.

— DAI-KOU.—A correspondent asks what is the botanical name and description of this very large Radish-like root so called by the Japanese. He states that a traveller has suggested it would be valuable as food for cattle.

— WE are informed that Mr. Clark, gardener, Whitley Park near Tynemouth, was very successful last winter in FORCING THE COMMON WOOD HYACINTH. He simply lifted clumps of bulbs from the ground, potted and placed them in the forcing house, and treated them as ordinary forced plants. It stands well when cut, and is invaluable for mixing with all kinds of white flowers.

— "CORNISH SUBSCRIBER" writes as follows on CRICKETS ON CUCUMBERS—"Twelve months since I erected a forcing house for the growth of Cucumbers. As soon as forcing was commenced I heard a cricket or two. No notice was taken of them at the time; now the house is swarming with them. They eat the leaves, but worst of all they bite the fruit, the least touch turning the Cucumbers very crooked, and I have scarcely one straight. If anyone can inform me through the Journal of a good method of extirpating the pest I shall be very grateful."

— GARDENERS or horticulturists who visit NEWCASTLE-ON-TYNE this summer may spend an enjoyable, easy, and profitable day by leaving that town by the 10.25 A.M., book for Pensher or Fencehouses. If the former, after a short walk you arrive at Beddick Hall, the seat of Mr. Morton, a fine old-fashioned place; from thence Lambton Castle is easily reached. A quick half hour's walk takes you from thence to Chester-le-Street, close to which is the celebrated Red Rose Vineries of Mr. Witherspoon. Southill, the residence of Lindsay Wood, Esq., is highly worthy of a visit, and can be easily reached in twenty minutes by walking from the Red Rose Vineries, and the scenery is perhaps not excelled in the north of England. Mr. Thomson is the able gardener at Southill, and has much to show the friends who visit him. A train returns from Durham at about 8 P.M., which speedily conveys you back to Newcastle.

— "R. P. B." sends the following observations on THE WEATHER IN SCOTLAND:—Two or three days in the beginning of June were remarkable for the heat, over 80° in the shade having been registered on the hottest day. The second week has been quite as remarkable for its cold. Hailstorms have been prevalent in the north of Scotland, and frosts have done much damage. On the 10th inst. occurred the most disastrous frost in this neighbourhood. The Vegetable Marrows only have been destroyed here, but much damage has been done to Potatoes in some positions. In one market garden the whole of the early Kidney Potatoes, which would have been ready for market in a fortnight, were cut down. In fields there has also been much damage; and the Turnip crop, which in Scotland is one of great importance, has received fresh injury. This has been an extremely bad season for germinating Turnip seed, on account of the ravages of the fly.

— AT the autumn Show of the North Otago Horticultural Society held on April 17th, the principal prizetaker was Mr. ADAM FORSYTH, late of Stoke Newington, gardener to the Hon. M. Holmes, who obtained the cup offered by His Worship the Mayor of Oamaru, for the taker of the largest number of prizes.

— A REMARKABLY distinct plant for the base of a rockery or borders is DIPHYLLEIA CYMOSA, a member of the Barberry family. The stems are 2 to 3 feet high, each bearing near the summit two large bi-lobed and irregularly cut bright green leaves, and terminating in a cyme of a dozen or more white flowers about half an inch in diameter, containing six oval petals and the same number of stamens bearing bright yellow anthers. The plant is a native of Carolina and Virginia, where it has been found at considerable elevations on the banks of small streams. It will be seen from this that it requires a moderately moist position, where its creeping roots can spread freely.

— ANOTHER pretty rock plant is ERINUS ALPINUS, which at this season of the year brightens many a nook with its purplish pink flowers. It is of dwarf habit, usually attaining a height of 6 or 7 inches. It has small irregularly toothed leaves and racemes of neat flowers, which but for their five petals might be taken from their general appearance to be related to the Cruciferous plants instead of the Scrophularias, their true relatives. The plant succeeds well in a light compost of peat, loam, and sand, and is admirably suited for little recesses of the rockery, where it becomes established if due provision is made for carrying off superabundant moisture.

— WE learn that Mr. W. H. Cloake is now the manager of the metropolitan establishment of Messrs. Thomas Green & Son, Blackfriars Road, the eminent horticultural engineers of Leeds and London.

— MR. EDWARD WILSON writes:—"Having seen my appointment recorded on page 444, I wish to correct the address. Instead of 'Highfield,' Bickley, it is Fernside, Bickley, Kent."

— WE have received a draft of the proposed CATALOGUE OF EXHIBITION ROSES that is to be published by the National Rose Society, and which will no doubt be useful when completed. One hundred and twenty Hybrid Perpetuals are enumerated, and forty-six Teas and Noisettes, but spaces are left for the addition of any other varieties which may be thought worthy of being admitted. The particulars concerning each variety are to be arranged in seven columns under the following heads:—Correct Spelling of Name, Date of Introduction, Raiser's Name, Form of Flower, Colour of Flower, Habit of Growth, and Distinguishing Characteristics. Rosarians will anxiously await the appearance of this work, which if well executed will supply a want felt by many cultivators of their favourite flower.

— A FEW weeks ago we observed a very pretty example of SPRING BEDDING in Mr. C. Turner's nursery at Slough, and though there was no attempt at elaborate arrangement the simple tasteful disposition of the distinct colours in lines produced a pleasing effect. This was particularly noticeable in the central walk that extends through the nursery, where the principal features were the rows of that old but useful bright yellow Wall-flower Belvoir Castle, the bright pink dwarf *Silene acaulis* literally a mass of flowers, the handsome rich-coloured *Viola Clevedon Purple*, the bright-tinted *Viola Blue Bedder*, with marginal lines of double white and crimson Daisies. In other portions of the nursery were some large and beautiful beds of the two *Violas* named above with various edgings.

— A DUBLIN correspondent writes to us as follows on FROST IN JUNE:—"Mr. Bedford, gardener at Straffan, Co. Kildare, was here to-day (9th). He told me the thermometer was 10° below freezing last night, and the frost has injured many bedding and other plants. Ten degrees of frost in 'rosy June,' and in Ireland too, is a phenomenon. We have had heavy but not long-lasting hailstorms during the week, but being rather sheltered and near the sea we do not feel the frost so much as they do further inland."

— WE have received the very unpretentious schedule of the WIRRAL ROSE SOCIETY, the Show of which will be held at Birkenhead on July 16th. In the open class for seventy-two varieties the prizes are £8, £6, and £4. In the amateurs' classes of thirty-six and twenty-four blooms, plate of the value of £10, £5, and £4 are offered, and silver and bronze medals and plate are provided for local exhibitors. The Society's Show last year was one of the finest of the season, and an earnest endeavour appears to have been made to command success this year.

— MESSRS. CASSELL, PETTER, & GALPIN send us the following parts, forming a continuation of some of their serial works. "Paxton's Flower Garden," part 10, which contains an excellent and faithful coloured representation of *Anthurium Andreanum* with descriptive notes. A coloured figure of *Viburnum plicatum* is also given, but scarcely does justice to the plant. In the "Gleanings" are woodcuts of *Luvunga scandens*, *Arnebia echioides*, *Hedychium chrysoleucum*, *Siphocampylos orbignyanus*, *Gaultheria Lindeniana*, *Dianthus cruentus*, *Echeandra terniflora*, and *Lilium Wallichianum*. "Familiar Wild Flowers," part 51, has plates and description of the Yellow Water Lily, *Nuphar lutea*, and the Shepherd's Needle, *Scandix pecten*. "Familiar Garden Flowers," part 28, gives coloured figures of *Begonia intermedia* and *Crataegus oxyacantha*, with cultural and historical notes.

— *Nature* states that "a monument of the celebrated NATURALIST, FREIHERR VON SIEBOLD, was unveiled in the park of the Vienna Horticultural Society on April 22nd last. The monument is 4 metres high, and is in the form of an obelisk with a granite pedestal. The upper part is formed by a very ancient memorial stone ornamented with floral designs, which was originally sent to the Vienna Exhibition by the Japanese Government, and was afterwards destined for this monument. Below this stone is a slab of marble bearing an excellent bas-relief of Siebold, the work of Schwanthaler. The whole monument is surrounded by living Fir trees, which were obtained from the Rax Alpe." The same journal announces the death of "MR. JOHN SANDERSON, one of the oldest colonists of Natal, and well known to European botanists as an ardent explorer of the South African flora. His name is commemorated by the beautiful genus *Sandersonia*."

— A CORRESPONDENT sends the following clipping respecting FRAGRANT CAMELLIAS—"The Vienna *Vaterland* reports that the gardener attached to the Palazzo Ferentino at Naples has, after the labour of years, succeeded in raising Camellias

having a distinct and fragrant perfume. The perfume is described as somewhat resembling Jonquil, and as being very delicate. The flowers themselves are of a tender pale rose tint, and it is only in flowers of this colour that the agreeable fragrance has been hitherto obtained, although the gardener has endeavoured to impregnate white Camellias with it."

## ROYAL HORTICULTURAL SOCIETY.

JUNE 14TH.

NEW plants, Pyrethrum blooms, with several miscellaneous groups of Orchids and other plants, constituted the chief features of this meeting, and visitors found sufficient to interest them both in the Council-room and conservatory.

**FRUIT COMMITTEE.**—Harry Veitch, Esq., in the chair. Exhibits in this department were not very numerous. Mr. R. Gilbert, The Gardens, Burghley, sent a Melon named Burghley Pet, a green-flesh fruit, of moderate size and well netted. It was considered by the Committee a very promising variety, and they expressed a desire to see it again. Fruits of a large Tomato named Conservative Chief from the same exhibitor were admired, and it was recommended to be tried at Chiswick. Some fine clusters of Gilbert's Criterion Tomato were also shown, said to be a seedling from Jackson's Favourite crossed with Vick's Criterion. The fruits were small but very abundant. Mr. Woodbridge, The Gardens, Syon House, Brentford, was awarded a cultural commendation for a dish of well-ripened British Queen Strawberries. Mr. Z. Stevens, The Gardens, Trentham, again sent examples of Trentham Early Fillbasket Tomato, and the Committee confirmed the opinion they previously expressed concerning it. Messrs. T. Rivers & Son, Sawbridgeworth, sent fruits of an early Cherry named Guigne d'Annonay, which somewhat resembled Frogmore Early. The tree was said to have been grown in an unheated orchard house. It was shown with May Duke for comparison, and a first-class certificate was awarded for it on account of its earliness. Specimens of Early Favourite Plum were also sent by the same firm from a tree in a pot which had been placed in a house on March the 27th. A vote of thanks was accorded. Messrs. J. Veitch & Sons, Chelsea, exhibited some extremely large stems of Stott's Monarch Rhubarb; and Mr. J. F. Wilkinson, gardener to Viscount Gage, Lewes, sent a seedling Melon. From Chiswick fruits of Noire Précoce de Strass Cherry were sent, the variety being said to be very prolific.

**FLORAL COMMITTEE.**—J. McIntosh, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, had a group of new and choice plants of considerable interest, including the following:—A white form of Azalea Souvenir de Prince Albert, very free and of good habit; Lilium Kramerii, a neat species with pale pink-tinted flowers; Heliconia aureo-striata, having neat ovate leaves veined with yellow; Carnation Lady Musgrave, a handsome variety, bearing large, full, deep scarlet flowers; Cypripedium selligerum majus, a remarkably fine variety with flowers of great size, the upper sepal being particularly broad; Calanthe Textori, a pretty species with white flowers, the lip blotched in the centre with orange red; Epidendrum falcatum, a curious Orchid, with white three-lobed labellum and narrow yellowish sepals and petals; Hydrangea Mariesi, a fine form, with large globular heads of lavender-blue flowers; Pratia angulata, a hardy plant, also known as Lobelia littoralis, of prostrate habit, with diminutive leaves and abundant white flowers; Spargula pilifera aurea, a form of Spurrey with yellow leaves; several Masdevallias, including M. coccinea and M. ignea, the latter especially bright; Cattleya Wagneri, a white-flowered form, resembling C. Mossiae; C. Mossiae alba; and a group of Tuberous Begonias, chiefly seedlings raised from B. Davisii, very free in flowering, and including some rich shades of scarlet. B. gigas and B. Mrs. Gilbert were two varieties of the ordinary type, with very large well-formed flowers—the former orange scarlet, and the latter of a deeper colour.

A vote of thanks was accorded to Messrs. H. Cannell & Son, Swanley, Kent, for eight stands of double Pyrethrums, comprising forty varieties, including many of great excellence. Some of the most noteworthy were Lizzie Macfarlane, white; Maximum plenum, bright pink; Progress, rich crimson; Mrs. Dix, neat pink; Rose Marguerite, fine rose; N. Twardy, full neat flower, rosy crimson; Wilhelm, good pink; Madame Billiard, neat white; Anemoniflorum sanguineum, very bright crimson; Multiflorum, rosy crimson; Boule de Neige, pure white; and Amphitrite, bright rose. Some fine varieties of Foxglove were also shown.

Messrs. John Laing & Co., Forest Hill, had a fine collection of Caladiums and Tuberous Begonias. The best of the former were candidum, similar in marking to argyrites, but much larger; Madame Lemoinier, with broad handsome lemon red in the centre, and pale green round the edge; and Mithridate, described below. Among the Begonias Mrs. Robert Whyte, scarlet, was noteworthy for the great size of the flowers; Captain Lambert, similarly large, but more brilliant in colour; and Exoniensis, a remarkably handsome variety, with extraordinarily large orange-scarlet flowers. A stand of blooms was also contributed of a great variety of colours from pure white through yellow, buff, orange, and scarlet; some rose tints also being represented. A vote of thanks was accorded to Mr. J. Croucher, gardener to J. Peacock, Esq., Sudbury House, Hammersmith, for a plant of

Odontoglossum crispum variety delicatum, the flowers of good size, white faintly tinged with purple. A plant of a variety of Cattleya Mossiae named aurosum was sent by the same exhibitor. Mr. James, The Castle Nursery, Lower Norwood, sent a plant of Odontoglossum cordatum aureum, differing from the type in the yellowish tint of the flowers. E. G. Loder, Esq., Floore, Weedon, Northamptonshire, exhibited a similar group of hardy Cacti to that he had at the great Show, which is mentioned on another page. Echinocactus Fendleri and E. gonacanthus were certificated.

Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley, exhibited flowering sprays of the two handsome climbing plants Stigmaphyllon ciliatum and Bauhinia corymbosa. The former has umbels of bright yellow flowers and cordate spiny-margined leaves; and the latter has corymbose heads of small pinkish white flowers, the stamens very bright pink, and the leaves of the characteristic two-lobed form but very small. A vote of thanks was accorded for the Stigmaphyllon, and a cultural commendation for the Bauhinia. M. H. Voss, Esq., De Montfort House, Streatham, exhibited a plant of Odontoglossum citrosimum Vossii, a pretty form, the petals and sepals of which are pure white, and the lip of a mauve purple tint. Large flowers of Phalaenopsis grandiflora were also staged. Mr. H. Hooper, Vine Nursery, Bath, sent a collection of Pyrethrum and Pansy blooms, the latter including two very striking varieties; a Fancy named Novelty, and a velvety black Show named William Dean. Mr. H. Coppin, Shirley, Croydon, sent several plants of Tuberous Begonias, representing very fine varieties. The best were Thebais, scarlet, very large; Pink Pet, pale pink, large rounded petals; Snowflake, white, of moderate size, and Cetewayo, of the Pearcei type with large orange-coloured flowers. Mr. C. Kimbeley, Stoke Nursery near Coventry, exhibited plants of a bright pink-flowered Pelargonium of the Christine type, named Empress of India, very free in flowering and of good habit. A neat tricolor Pelargonium called Empress was also represented. Mr. Wilkinson, gardener to Viscount Gage, Lewes, contributed a collection of Gloxinia blooms mostly of the drooping section, diversified in colours but not remarkable in size. A vote of thanks was accorded. Mr. T. Dale, Orchid grower to E. Edwards, Esq., Blackwater, sent a plant of Cattleya gigas with very large flowers, the lip of a very rich crimson tint.

Mr. J. Croucher contributed a tasteful group of Orchids, including good examples of Odontoglossum vexillarium, with very richly coloured flowers; Masdevallia Harryana sanguinea has large deeply coloured flowers; Brassia verrucosa, with eighty spikes; and a central plant of Oncidium ampliatum majus, with a very large spreading panicle of bright yellow flowers. Other noticeable plants were Lycaste Deppel, with over two dozen flowers, and Odontoglossum candatum. A silver Flora medal was awarded. Mr. Ebbage, gardener to J. S. Bockett, Esq., The Hall, Stamford Hill, was awarded a silver-gilt Flora medal for a handsome group of Odontoglossum Alexandrae, comprising some very fine varieties. One spike had ten flowers of unusual size, and all the plants were in fine healthy condition. Silver Banksian medals were awarded to the following:—Mr. James, The Castle Nursery, Norwood, for a collection of Orchids, including a fine potful of Epidendrum vitellinum, several Dendrobies, Odontoglossums, and Oncidiums; Messrs. Barr & Sugden, for a pretty group of hardy flowers, Irises and Pyrethrums being particularly numerous and bright; and Mr. Hooper of Bath for several stands of handsome Pyrethrum, Pansy, and Ranunculus blooms, including a good selection of varieties.

First-class certificates were awarded for the following plants:—

*Carnation Lady Musgrave* (Veitch).—A handsome Tree variety, with very large, full, dark scarlet flowers  $3\frac{1}{2}$  inches in diameter. Very effective and free.

*Sarracenia melanorrhoda* (Veitch).—A hybrid between S. Stevensii and S. purpurea, with leaves 6 to 8 inches long, of a deep reddish colour.

*Cypripedium selligerum majus* (Veitch).—A variety of this fine species with very large flowers, the upper sepal being particularly striking owing to its great breadth and rounded form.

*Hydrangea Mariesii* (Veitch).—A beautiful Hydrangea with globular heads of lavender-blue flowers. The colour is very delicate and pleasing, and the plant appears to be of good habit.

*Coleus Miss Simpson*.—This and the following were from that successful raiser Mr. King, gardener to G. Simpson, Esq., Reigate. A very handsome variety with a large neatly-formed leaf, the centre being bright crimson with a tinge of scarlet, margined with bright yellow, and neatly crenated. The brightness of this variety was remarkable, and it was greatly admired.

*Coleus Mrs. Stiedall*.—A variety of dwarf compact habit; the leaves tapering, bright rose in the centre, deeply crenated, mottled with deep brownish maroon near the margin, and edged with green. Very distinct and attractive.

*Caladium candidum* (Laing).—A pretty variety, with neatly formed leaves 7 inches long by 4 inches broad, veined with green and white, suggestive of C. argyrites but much larger than that form.

*Caladium Mithridate* (Laing).—Leaves unusually large, a foot in length and the same in breadth, deep red in the centre and dark green at the edge. A very handsome variety.

*Caladium J. R. Box* (Laing).—Very distinct, of a semi-transparent texture strangely veined with red and green. These are three fine and distinct Caladiums well worth including in collections.

*Echinocactus gonacanthus* (Loder).—A Cactaceous plant with short

globular fleshy stem studded with large white spines, and bearing bright orange nearly scarlet flowers.

*Echinocactus Fendleri* (Loder).—Similar to the above in habit, but with more numerous smaller spines, and rosy purple flowers.

*Lilium Washingtonianum* Scott Wilson.—A Lily raised by G. F. Wilson, Esq., Weybridge, from seed of *Lilium Washingtonianum* sown in September, 1873. The flower is neat in form with yellowish recurved petals spotted with chocolate, the leaves being precisely those of *L. Washingtonianum*, while the flowers are very distinct.

The Pelargonium Society also awarded certificates for the two

following varieties from the Royal Horticultural Society's garden. They were both raised by M. Lemoine.

*Pelargonium Charles Darwin*.—A zonal variety, with large umbels of double flowers of a peculiar bright rosy hue, with a tinge of purple.

*Pelargonium Seedling 29*.—An Ivy-leaf form, with pale pink double flowers in moderately large compact trusses. The leaf is small and neat.

SCIENTIFIC COMMITTEE.—Rev. G. Henslow exhibited monstrous forms of *Cardamine pratensis*, in which double flowers were issuing from the side of ovoid ovaries remaining after the flower had fallen.

Fig. 103.—*AQUILEGIA STUARTII* (STUART). (See page 490.)

They were received from Mr. Gibbs of Chelmsford. Blossoms of *Lychnis Githago* in which numerous flies had been entangled by the long hairs and perished, illustrating Dr. Kerner's theory of the various methods by which "unwelcome guests" are excluded from flowers. A Daisy with ligulate florets issuing from near the centre of the disk florets, forwarded by Tinson of Holloway. Impressions taken from the cut end of Water Lilies appearing to afford a natural dye, by which the exact representation of the lacunæ or air-passages could be made. A pitcher-like leaf of *Masdevallia Lindenii* was exhibited by Mr. James of the Castle Nursery, Lower Norwood.

Mr. Owen of Knockmullen, Gorey, Ireland, forwarded "Jack-in-the-Green" Polyanthus, several instances having occurred with remarkably large sepals; leaves of *Sarracenia flava Drummondii*, and which

had failed to form pitchers; variety of *Viburnum lucidum*, which appears to be much hardier than the usual form. Mr. Owen remarks that about the only loss last winter was the common Fuchsia, though the frost of June 8th cut the Potatoes.

*Diseased Rose Leaves*.—Mr. J. Tinsley forwarded some Rose leaves which are falling from his trees till some are quite bare. They were referred to Mr. W. G. Smith for report.

Mr. Wilson exhibited a fine hybrid Lily between *L. Washingtonianum* and probably *L. Columbianum*. It was from seed sown in 1873, and possessed the foliage of the former species, but had a very distinct flower.

Mr. E. Giles Loder exhibited a fine series of Cacti from the Rocky Mountains, and said to be perfectly hardy. Many were in blossom.

Some were collected at an elevation of 10,000 feet. Many appear to be new to cultivation. He measured plants of *Echinocereus phoeniceus* 13 feet in circumference! A vote of thanks was given unanimously to Mr. Loder for the exhibition of his interesting collection.

LECTURE.—The Rev. G. Henslow commenced his lecture by describing the carnivorous habits of *Sarracenia*, a hybrid plant having been exhibited by Mr. Veitch. He alluded to the different kinds, such as *S. purpurea* and *S. flava* with opened mouths, and *S. variolaris* with a closed one, thus excluding the rain which is caught in the others. The surface of the lid and lip is covered with honey glands, which attract insects, and apparently stupefy them, so that on crawling inwards over the deflexed spines on the surface they get detained by the long needle-like processes below. Though the circumstances under which a digestive fluid is secreted is not thoroughly known, there is but little doubt the carnivorous habit benefits the plant in the same way as it does our English Sundew. A fine blue *Hydrangea Mariesii* from Japan was commented upon, the lecturer remarking that the *Hydrangeas* of Jersey are almost invariably blue, but the cause had not been definitely found out. The origin of the large neuter blossom was explained, one of the natural forms being exhibited where the central flowers are minute and perfect, but those on the circumference of the bunch are neuter, being composed of an enlarged calyx, the flower remaining abortive within. Some Cactuses were alluded to as interesting as being perfectly hardy rock plants from Colorado, some from an elevation of 10,000 feet. They were shown by the collector, Mr. E. Giles Loder of Weedon, Northamptonshire. Double *Pæonies* and *Ranunculus* furnished remarks on the various methods of producing double flowers. In one *Pæony* there was a repetition of corolla and stamen twice over, no pistil being in the centre. In another the carpels and stamens were all changed into petals, but they had assumed different forms respectively. *Iris*, *Gladiolus*, *Sparaxis*, and *Ixia* illustrated the family *Irideæ*, a fine group of which was exhibited by Messrs. Barr & Sugden. The lecturer described the various processes of fertilisation, showing how different they were in each case, yet all belonged botanically to one and the same family.

#### AQUILEGIA STUARTII.

A SHORT time ago a flower of this *Aquilegia* was submitted to us by the raiser, Dr. Stuart, of Hillside, Chirnside, N.B., for our opinion relative to the merits of the variety. As it is one of the finest, if not the very finest, of the *Columbines* with which we are acquainted, we decided to have it engraved. The figure on page 489 shows the character of the flower and its striking contrast in colour; but the richness of the sepals and the purity of the tubular petals must be seen to be appreciated, the former being a rich violet blue with a satiny gloss, and the latter ivory white with deep coerulean blotches. This beautiful variety is the result of a cross between *A. glandulosa* and *A. Witmanniana*, the latter being the pollen-bearer. It was exhibited on the 25th ult. at a meeting of the Berwickshire Naturalists' Club, when it was named by Professor Balfour of the Edinburgh University. Dr. Stuart informs us that the "batch of seedlings have flowered in the open air, and were exposed to the extreme temperatures we experienced in this region during the winter without any protection whatever. Every one acquainted with *Aquilegia glandulosa* (true) knows what a shy flowerer it is. On about a dozen plants of this hybrid I counted one hundred blooms in good order at one time. It is of a darker blue in colour than *A. glandulosa*, and the individual blooms are of larger size. The foliage resembles the parent. I consider it a refined and at the same time a robust and free-flowering variety of *Aquilegia glandulosa*, and as such an acquisition as a hardy herbaceous plant." We congratulate Dr. Stuart on having been successful in adding such a handsome variety to a fine old genus of border flowers.

#### NOTES ON POTTING PLANTS.

ONE of the most important operations connected with plant-growing, and which unfortunately is often unskilfully performed, is potting plants. Amateurs may glean from calendars of operations when and what to pot afresh, but it is difficult to convey in a few words exactly how the work should be done in all cases. Very few kinds of plants are identical in their requirements, and it is for the want of this knowledge of what should be done that proves fatal to many much-loved plants. Cultivators, especially those living in towns, are generally at a great disadvantage with regard to suitable composts. We may recommend turfy loam, peat, and other special soils, but the question is, Where are they to be obtained? The former is not always to be had at a reasonable price; but the latter, and which for a few kinds of plants is indispensable, can certainly be bought in small quantities and of good quality. Those who have spent considerable sums of money on *Ericas*, *Epacris*, *Azaleas*, *Bouvardias*, *Camellias*, and other

hardwooded plants must not begrudge a small sum for suitable soils for them. To attempt to grow them in soil consisting principally of loam, perhaps fibreless and having previously been used in hotbeds, will only end in the loss of the plants. Any of the free-growing softwooded kinds of *Heaths* and the varieties of *Epacris* that have been cut back and are now breaking afresh, should, unless repotted last season, be shifted. Suitable soil consists of two parts good peat, one part each of fibrous loam and sifted leaf soil, with a liberal addition of sharp sand and charcoal. As small shifts only must be given, the soil should be broken up somewhat finely, and it ought not to be either very dry or very wet; the pots used to be perfectly clean and drained carefully, commencing with a large corner piece of potsherd, surrounding this with other large pieces, covering these with much finer pieces, and placing over them a thin layer of moss. Should the soil of the plants to be potted be in a sweet condition and therefore full of healthy roots, the ball ought to remain intact with the exception of the removal of old drainage, and be transferred to a pot of a size to admit of no more than an inch of fresh soil all round. Before potting carefully remove with a pointed stick any sour soil on the surface of the balls, then place a little of the roughest soil on the drainage, next more soil, which, when firmly rammed, will raise the ball to near the rim of the pot. Gradually fill in the soil, rendering it firm with a stick, finishing off neatly to within the depth of the rim of the pot.

*Azaleas* are now growing freely, and as the roots also are commencing active growth, now is the time to shift such as may require it. Large specimens are not repotted often, but young healthy plants should be shifted at least every two years, and what has been recommended for the *Heaths* and *Epacris* is equally applicable to *Azaleas*. All will be materially assisted if placed after repotting in a slightly increased temperature, say in a vinery that is being closed early and syringed freely. Probably in amateurs' gardens there are more sickly than healthy *Camellias* and *Azaleas*, the cause of which may generally be traced to the bad root-action, this being the result of either unsuitable soil, defective drainage, excessive waterings, or all combined. Where the balls are found to be in this unsatisfactory state, on no account shift into larger pots, but carefully pick away the sour inert soil (usually that last given), trim off the dead roots, and repot the reduced ball into as small a pot as can be used. By these means only can such plants be restored to health, and there are many other kinds often to be met with that might with advantage be treated similarly. *Camellias* when in a healthy state are most safely repotted after the new growth is matured and the buds set. Being coarser-rooted, rougher compost should be employed. A rather larger pot may be employed, and the soil will not require to be made as firm as in the case of the finer-rooted plants. No particular compost is absolutely necessary for *Camellias*, but the less fibre the soil contains the greater is the need for liberal drainage and the addition of lumps of charcoal, or, as a substitute, broken potsherds, in order to keep the soil porous. A very suitable compost consists of equal parts fibrous loam and peat, with a slight addition of sifted decomposed manure and sharp sand. If really good fibrous loam is available peat may be dispensed with, employing three parts of loam to one of good leaf soil, with a small quantity of fine manure and sand or road grit. *Camellias* may even be grown in fine loam and leaf soil in equal parts, but much care must be taken with the drainage, covering the crocks with moss. The latter may also be used for the other soils, but in those cases some of the roughest of the soil is first placed over the drainage, and this tends to keep it clear. It must be added, however, that loam which contains lime is not suited for *Camellias*.

A mixture of two parts loam to one of leaf soil, with a small quantity of manure and either sand or road grit, is suitable for *Balsams*, *Fuchsias*, *Chrysanthemums*, *Carnations*, *Tuberous-rooted Begonias*, *Salvias*, *Cinerarias*, *Roses*, *Pelargoniums*, *Petunias*, and other common plants. As the majority of the foregoing are coarse-rooted the more fibrous the loam the better, and it should be broken up roughly. *Balsams* now growing in 3-inch pots may be transferred into 8-inch or 10-inch pots; *Chrysanthemums* may be shifted from 4-inch pots into 10-inch or larger for flowering; *Carnations* from 3-inch into 9 or 10-inch pots; *Tuberous-rooted Begonias* (strong roots) from 5-inch into 10-inch pots; *Begonia weltoniensis* from 3-inch into 6-inch or 8-inch pots; *Salvias* from 4-inch pots or larger into 10-inch pots; *Cinerarias* from 3-inch into 6-inch or 8-inch pots; *Roses* (spring-struck) from 4-inch into 9-inch pots; *Pelargoniums* and *Petunias* from 4-inch into 8-inch pots. These shifts may appear excessive, but if the after-treatment given be right, the results will be satisfactory and labour will be economised.

No plant should be repotted with the soil in a dry state, and

any found to be very dry should be well soaked in a pail or tub of water, and allowed to drain for a time previous to potting. The soil employed being in a moist state, fresh potted plants need not be watered for three or more days according to the weather; and for a time particular care must be taken not to give more water than is required, especially where liberal shifts were given, or the fresh soil will become sodden and sour, and altogether unsuitable for the reception of the delicate roots. At the same time the old balls should occasionally be examined, as they frequently become excessively dry although surrounded with moist soil. In this case a basin should be formed round the stem, and the soil be pierced with a wire skewer; small quantities of water may then be repeatedly given till the ball is properly moistened, without saturating the fresh soil. This may appear a small matter, but it is very important, and may save the life of many a valuable plant.

Those who possess a plant stove have special need of good soils for potting. The majority of heat-loving plants require a liberal quantity of good peat to root in. Many Orchids will thrive in a mixture of equal parts of turfy peat, sphagnum moss, and charcoal. As a general rule the pots for these plants should be at least half filled with crocks, and the plants raised above the level of rims. A compost consisting of two parts of roughly broken fibrous loam, one part each of peat and leaf soil, with a small quantity of decomposed manure and a good addition of sharp sand, broken potsherds, or charcoal, will be found suitable for Caladiums, Gloxinias, Begonias, Lycopodiums, Ferns, Coleuses, Crotons, Draecenas, Allamandas, Stephanotis, Cissuses, Bougainvilleas, Eucharises, and other similar plants. Much might be said on the subject of potting, but for the present we only advise the use of clean pots carefully drained; giving liberal shifts to those plants that are coarse-rooted, such as Crotons, Caladiums, and Allamandas.—I. M.

#### PRIZE BOILERS.

A CURIOUS accidental omission occurs in our report of the boilers that were exhibited at South Kensington on the occasion

Fig. 110.—Greens' Silver-medal Tubular Saddle Boiler.

of the great Show there. The apparatus to which the silver medal was awarded is described on page 462, but the name of the exhibitors, Messrs. Thomas Green & Son, Leeds, was not mentioned. As so much interest attaches to boilers, especially

Fig. 111.—Warhurst's Bronze-medal "Ben's Boiler."

to those for which prizes are awarded, and as it is impossible to explain the features of boilers without figures, we submit engravings of Messrs. Greens' silver-medal tubular saddle, and Mr. Warhurst's bronze-medal flued saddle boilers, so that our readers can comprehend their nature and form their opinions on their merits. Without saying a word against any other boilers

that were in competition, we have no doubt that those to which the Judges made their awards are strong, durable, simple, and quick generators of heat. The two figures now submitted, and the descriptions on the page quoted, will enable the two boilers in question to be fully understood, and it is not necessary, therefore, to refer to them at greater length.

#### GLASS STRUCTURES FOR AMATEURS.

**PLANTING VINES.**—The canes will have to be procured in autumn or winter, making choice of those with short-jointed well-ripened and moderately strong wood. Cut them back to such length that when planted there will be sufficient stem to reach to the trellis. Winter them in a cool house or in a shed, the roots especially being protected from frost. The soil in the pots must not be allowed to become very dry, but should be kept a little moist to secure the vitality of the roots. In March place them in the house, from which frost must be excluded, but not kept at more than a greenhouse temperature—viz., 40° to 45° artificially, ventilating at 50°, and fully above that temperature. Keep the canes upright to insure the upper eyes breaking first, and the soil moist. When the shoots from the uppermost buds are a couple of inches long turn the Vines out of the pots, carefully remove the soil from the roots, and spread them out as straight as possible, working the soil amongst them, and cover about 3 inches deep. Give a good watering at a temperature of 100° to settle the soil, and mulch with about 2 inches thickness of short manure. Syringe the canes two or three times a day—i.e., morning, early afternoon, and at about 5.30 P.M., and shade from sun until established. The house should be kept rather close, ventilating from 60°, and allowing an advance to 70° or 75°, closing early in the afternoon, but not so as to raise the temperature over 80°; the minimum or night temperature should be about 55°.

When the roots are working freely in the fresh soil, as will be known by the shoots growing freely, make choice of the best for training up the trellis, and stop the others gradually at the fourth to the sixth leaf, not rubbing them off as is often done, every leaf being of consequence in the manufacture of roots. These supernumerary growths may be allowed to remain until the leading shoot or cane is growing fast and is well advanced up the trellis, when they may be removed close to the rod without any fear of bleeding, not removing them all at once but by degrees. The main shoot should be allowed to make all the growth possible, and the laterals also should be allowed to extend, but must be kept down so as not to interfere with the principal leaves, especially at the bottom of the trellis. The cane may be stopped when the bottom of the trellis is reached, or in the case of a half-span or span when the full extent of the trellis is passed over.

Copious supplies of water will be necessary, and the surface should be frequently damped to encourage surface-rooting; and besides sprinkling available surfaces in the early part of the day, the Vines should be syringed in the afternoon of fine days when the house is closed, which should be done early, the temperature, however, not being raised above 90°, and at night it should fall to between 60° and 65°, but no artificial heat need be employed after May.

By September the canes may be as thick as walking sticks (and there is a difference in those) and have eyes like nuts. The wood must be ripened and the eyes plump at least at the bottom of the trellis to the extent of about a yard. This may be effected by lessening the supply of water to the roots, and discontinuing the syringing as well as admitting air more freely, and leaving a little on at night so as to promote a circulation of air. The laterals also should be shortened, commencing at the bottom of the trellis and cutting them back by little and little until those at the first 3 feet of cane on the trellis are brought close in by October. The growths will as yet be active, which, however, it is little use encouraging; therefore remove part of the laterals and shorten others. If the wood early in October is not brown and hard, especially at the lower part of the trellis, fire heat must be applied, and the house ventilated day and night, which should be continued until the wood is ripe, the atmosphere being kept dry, and no water given at the roots except to keep the soil moderately moist. Either the wood will be ripe in November or never, and the house should be freely ventilated except during frost, and the foliage will soon ripen and fall off.

When the foliage has fallen cut the canes down to a bud at about 3 feet from the bottom of the trellis, and at once have them washed with soap and water, and then dressed with an insecticide, the house having previously been thoroughly cleansed. The border, particularly near the stem of the Vines, should be given a top-dressing of turfy loam with about 20 per cent. of bone dust, the loose surface soil of the border having been scraped off, making

it moderately firm. The top-dressing must not exceed 3 inches in depth. The temperature through the winter should be kept at 40° to 45° on account of the plants, or if there are no plants merely exclude frost. We have then a clean house and Vines, and everything ready for a fresh start when the time comes, instead of house and Vines being dirty until the very last moment before starting.

In March of the second year depress the canes, bringing them well down so as to form an angle of at least 45° with the upright stem to the trellis, and keep them there, and damped two or three times a day until all the eyes have broken and the growths are about a couple of inches long, when the canes may be secured to the trellis. The shoot from the uppermost bud should be trained as leader, and treated precisely as the one of the previous year; and, as it will probably show fruit, do not allow it to remain. The side shoots on the rod (for it is one now) should be disbudded, leaving one growth say to the right at the bottom of the trellis, another on the same side at as near 18 inches above it as possible, and a third on the same side as near the leader as may be practicable. On the other side of the rod retain a shoot at 9 inches from the bottom and another 18 inches higher up, so that there will be five side growths and the leading shoot or cane. Remove all the others.

Upon each of the side shoots a bunch of fruit may be allowed, for with the leader allowed to extend roots will be plentiful and able to cater for the crop, provided food is supplied by watering. Stop the shoots at about 2 feet, which is half the distance between the Vines, and the laterals stop at the first leaf for the two first leaves next the rod, but the others may be allowed to make three or more leaves before pinching out their points. The future stopping must be regulated by the space, allowing no more foliage as regards the bearing part of the Vine than can be fully exposed to light. These side shoots will need at the winter pruning to be cut back to two buds, and are then spurs; the leading shoot or cane be shortened back as in the preceding season, but may be left a little longer, say 4 feet 6 inches, and afterwards subjected to the same treatment as the part below. In this manner the Vines will ultimately have rods with spurs or shoots, according to the time of year, on both sides at 18 inches distance apart, and their treatment as regards stopping will be the same as for the first-formed side shoots. The only difference will be that two instead of one shoot will be originated from each, one of which only must be retained, the other being rubbed off so soon as the best show of fruit is discernible.—G. ABBEY.

#### KITCHEN GARDEN.

CUTTING Asparagus should not be continued longer than is absolutely necessary, as it is very important that the plants have sufficient time to make good growth and allow the buds for the ensuing season's supply to become matured. Abundant supplies of liquid manure may be given, and in exposed situations it is advisable to secure the stems to stakes a few feet distance apart and connected by tarred string. Seakale must be kept from seeding, and if the crowns are very much crowded thin them so as to leave two or three to each strong root. Liquid manure will assist the growth, similar remarks applying to Rhubarb. Peas should be copiously watered. When the plants in later crops are too numerous thin them out to about 2 inches apart. These may be well mulched with litter or manure and staked as soon as fit. Early Peas may yet be sown. Afford water abundantly to Scarlet Runners, and see that they are mulched with littery manure. Earth up the earliest Celery, plant out for succession, prick out young plants from beds for late supplies, and prepare trenches, the space between them being appropriated for Lettuce or summer Spinach. Take advantage of favourable weather to plant out Cauliflowers, Savoys, Brussels Sprouts, and Broccoli as ground becomes vacant. Maintain successional supplies of Turnips by occasional sowings as required, also Radishes and Lettuces. Sow Endive for early use; the Round-leaved Batavian and Green Curled are the best. Those earlier sown should be attended to in transplanting before they become too large. Sow Rosette Colewort, prick

off the seedlings when large enough, and eventually plant 15 inches apart every way. This is very valuable for winter use. Sowings of French Beans may still be made as necessary. Globe Artichokes in bearing, also those planted in spring for autumn supply, will require abundance of water to prolong the bearing season. Vegetable Marrows and Ridge Cucumbers must now be earthed up, pegging the shoots at equal distances apart over the surface of the ground, the glasses or other covering being removed or the handlights raised.

#### FRUIT HOUSES.

*Melons.*—Sowings may still be made according to the requirements of the establishment; and for frames and dung-heated pits a sowing now will, under favourable conditions, produce plants that will yield a supply of ripe fruit towards the close of September. Those having light well-heated houses may continue sowing until the middle of July in order to maintain the supply up to November. A good bottom heat should be secured to young plants about to be turned out, and this will lessen the necessity for fire heat, of which only a little by night will be required. Remove laterals freely where the fruits are fast swelling, and afford support to such as are becoming heavy. Maintain a temperature by artificial means of 70° to 75°, affording water or liquid manure abundantly to those with fruit swelling off. Maintain a moist atmosphere, syringing the foliage moderately at closing time; shade only to prevent flagging. In pits and frames with the fruit coming in afford the full benefit of the sun, with a free admission of air and very little water. Continue attention to instructions in previous calendars with respect to fertilising the flowers, also bestowing liberal attention in stopping, training, thinning, and earthing-up after the fruits have set.

*Vines.*—Cold nights still necessitate the use of fires, but they must be extinguished early on fine mornings, when ventilation will require careful attention, admitting air at the top of the house, gradually increasing the supply as the sun gains power; and when the maximum temperature has been reached the front ventilators may be opened, but cold draughts or sudden depressions of temperature must be carefully guarded against. Copious supplies of tepid water will be needed by inside and outside borders; liberal mulchings in dry seasons also encourage surface-rooting. Proceed with thinning late Grapes, and maintain abundant moisture to assist the swelling and prevent the attacks of red spider. Keep laterals well stopped after the space is covered with foliage. Newly planted Vines which are growing freely must be encouraged to make as many branches as possible by closing the house early, syringing freely on fine afternoons, and keeping the surface of the border moist.

*Cucumbers.*—Fire heat as yet cannot be dispensed with at night. Examine the plants weekly, well thinning out the old growths, and afford copious supplies of liquid manure twice a week. Syringe at closing time, but avoid morning syringing, maintaining, however, a moist atmosphere all day in bright weather to secure a healthy and fruitful growth. Pits and frames should be watered and closed about 4 P.M., or earlier, according to the weather, affording liquid manure occasionally.

#### ORCHARD HOUSE.

Insects are now troublesome, and in order to prevent them spreading syringe the trees every afternoon with the garden engine. It is important that this be done sufficiently early to allow the foliage to become dry before nightfall. If the syringe fails to keep the aphides in check recourse must be had to fumigation. The shoots of the Cherry trees infested with black aphides should be dipped in tobacco water, and whilst wet rubbed gently with the fingers, as the insects have the property of throwing off the water, syringing well the following morning. Syringing with clear water will mostly be sufficient to prevent the increase of red spider; but if not, syringe with nicotine soap at the rate of 3 ozs. to a gallon of water. Attend to the requirements of the trees in stopping and removing superfluous growths. Afford water, and if necessary liquid manure abundantly, surface-dressing with rich material. During warm weather the ventilators may be allowed to remain open at night, taking care to close them on cold nights, especially when high winds prevail.

#### FLOWER GARDEN.

Roses are growing freely at last, and should be examined frequently

for grub and aphides, unfolding any curled leaves, and syringing with tobacco water, a gallon of juice being sufficient for six of water, adding 2 ozs. of soft soap to every gallon. As the weather is dry syringing will be beneficial, supplying liquid manure and mulching with short manure. Climbing and pillar Roses should be neatly tied to their supports, removing all decayed flowers. Climbers and other wall plants must have their growth regulated, thinning them where too crowded and laying in wood as necessary, giving a good washing with the garden engine to cleanse the foliage of dust and insects.

The stock of spring-bedding plants now requires attention. Double Daisies, Primroses, Polyanthus, and Auriculas may be divided and planted out on a partially shaded border. Cuttings of Pansies and Violas inserted on a shady border will soon root and make strong plants by autumn. *Myosotis dissitiflora* may be treated similarly. Prick out seedling Wallflowers, Antirrhinums, and other perennials intended for spring and early summer flowering. Insert cuttings of double Wallflowers, Rockets, and Sweet Williams on a north border or under a handglass. Sow Brompton and Intermediate Stocks on a north border. Prepare pipings of Pinks, and insert them under handlights. Sow Hollyhock seed in rich light soil, and prick off earlier seedlings. Dahlias and Hollyhocks require stakes; any of the latter for showing should be trained with one stem, reserving the most promising. Make a final sowing of Mignonette and Sweet Peas.

Herbaceous plants need constant attention in staking and tying as they advance in growth. Avoid bundling the growths, as the plants are never seen to advantage, the stems being drawn and many of the principal leaves destroyed by depriving them of light and air. When one stake only is employed the branches should be looped up separately. Before staking remove the weakest shoots, thus concentrating the vigour in those retained. Any of the stronger growers will be benefited by liquid manure and a mulching of manure. Plant out late-sown Stocks, Asters, and Zinnias in well-enriched soil, and when they are established mulch with short manure. Annuals sown in masses in beds or borders should be freely thinned out and not allowed to suffer from drought, or they will grow weakly and flower poorly.

Calceolarias, Verbenas, and Violas may have their growth promoted and the flowering prolonged by a surface-dressing of short manure. Attend to bedding plants in watering, removing bad leaves and decayed flowers, pegging down such as require it, and secure sub-tropical plants to stakes.

#### PLANT HOUSES.

*Greenhouse.*—Fuchsias that began to flower early should now be regularly supplied with liquid manure, and well syringed every afternoon to keep down thrips and red spider. Plants required for flowering at the end of August or beginning of September may be plunged out of doors in a sheltered but sunny position, keeping the shoots stopped, and they will make compact growth. Due attention must be given to training, and occasional applications of liquid manure will be advantageous. Cockscombs must after the flowers show be liberally supplied with liquid manure, keeping them near the glass in a pit or frame, where they can receive a little heat and abundant moisture. Late Balsams should be potted and grown on, as they will be useful late in summer.

Petunias in small pots may be shifted into larger sizes, and they will be useful in autumn. Turfy loam, with a fourth of well-decayed manure or leaf soil and a little sand, suit them well. Avoid over-potting; 6 or 7-inch pots are large enough.

Vallotas should be well supplied with water and liquid manure, and have light airy positions, so as to mature the growth. In order to obtain late flowers plants may be placed out of doors in a sheltered position, keeping them duly supplied with water, removing them to a house in September or when the flower scapes appear.

Kalosanthes may be placed outdoors in the full sun to insure the maturing of the growth. They must not be allowed to shrivel, and if in small pots they should be plunged in ashes to prevent the soil becoming dry too quickly. Cactuses may be similarly treated.

*Clianthus Dampieri* deserves a place amongst the most select plants, but it is impatient of being repotted after it attains a good size, and

should therefore be transferred from the small seedling pots to 9 or 10-inch pots. Grow the plant in a pit or frame kept rather close, but not shaded through the summer, and in winter a warm greenhouse or intermediate temperature is suitable. It succeeds best in fibrous peat and an admixture of nodules of charcoal, and may have clear weak liquid manure when in free growth. A damp cold atmosphere is injurious, also excess of water, and if kept too hot in summer it falls a prey to red spider. Seed may be sown in gentle heat in 3 or 4-inch pots, and when the seedlings are a few inches high transfer them to the large pots.

## THE BEE-KEEPER.

### ARTIFICIAL SWARMING.

IN the calendar of operations for May I sketched in outline some modes by which we can most helpfully to ourselves and bees secure increase in the number of our colonies, but a request that further details should be given induces me to return to the subject.

All *habitués* of our bee shows are now acquainted with the operation of driving, constantly selected as it is for public display, since nothing we can exhibit to the uninitiated is more likely to excite astonishment, or is capable of subserving a greater variety of useful purposes for those who still adhere to the time-honoured skep.\* But the manipulation of frame hives, though much more simple and agreeable, is not so easily made part of the attraction of a bee tent, and hence needs the more careful explanation here.

By far the larger number of our bee-keepers are absent from their apiaries during the day, and to such anxiety grows with the prosperity of their colonies; for the dense population of the pet stock on which the brightest hopes are set, and for which the temporary super is already prepared, is quite likely to leave for "pastures new" while we are absent and no watcher is at hand.

That this kind of vexation can be reduced to a minimum so small as to be unimportant is certain, while it is also true that the most carefully and skilfully tended apiary may occasionally throw out a natural swarm quite against the will of its owner. In my own case this occurs about once annually from between twenty and thirty stocks.

Preparation for colonising consists of two steps—the raising of drones in number, and the starting of queen cells. If a stock is deprived of its queen the oft-explained process commences of selecting eggs or young larvæ, and then so laterally expanding the cell that those surrounding it are more or less obliterated. Dosing with immense quantities of food follows, and in due time (sixteen days from the egg-laying) a queen is produced; but when under normal circumstances with the queen present a swarm is determined on, the plan differs somewhat in some cases from that described, for I have indubitable evidence that at times the queen actually lay eggs in partially formed queen cells—cells, that is, that have been queen cells from their foundation day upwards. Some who have not spent more time than myself in examining this matter will tell me I am wrong I doubt not, but negative evidence cannot disprove the positive that I have in my possession. When these cells have reached the stage of sealing—*i.e.*, eight days before hatching into queens, the time of departure is at hand, and is only likely to be naturally delayed by a condition of weather so adverse as to disincline bees for travelling. Should this be prolonged the queen cells will be torn open and the occupants ejected, when swarming is not likely to be again attempted under two or three weeks. It is true that sometimes bees, Italians especially, will come out before commencing queen cells, but this is rather the exception that proves the rule.

Every bee-keeper knows that where natural swarming is practised, piping (the call-note of the young hatching queens) may be heard on the eighth evening after the departure of the swarm, and that casting takes place, if at all, with curious regularity on the ninth day. The rule already given explains the cause of this, and also supplies us with a ready means of getting a correct forecast as to the intentions of our stocks. If those that are getting crowded are run over every four or five days the presence of queen cells will forewarn us, while their absence will set us at rest till the next examination. The plan to be adopted if we desire to prevent swarming can only here be hinted. Cutting out

\* This operation has received its share of attention elsewhere in a reply to a correspondent, which see.

queen cells and supering, or clearing by the extractor a comb of honey from the side, and putting this in the centre of the brood nest, or, if honey is not at the time being yielded, simply shaving off the capping and inserting it centrally, will help us in our object; but we are talking of swarming now and not its prevention. Before explaining our methods, however, let us try to meet a possible objection. If supers are on and being filled, then swarming is most to be dreaded, and then the examination cannot be made; no, but due caution at the time of supering may have made the probabilities of swarming remote. If hatching brood was then made to occupy the centre of the hive while younger brood and eggs stood towards its end the natural process of maturation has constantly been opening new cells to receive the eggs, the queen is waiting to deposit, and the crowding of the brood nest, which is the bees' natural prompter to colonisation, has been prevented.

But we are intent upon making our swarm artificially. Our hive is very strong, and either cells are growing, or we have some ripe ones, or, better still, a queen already laying waiting for insertion. The swarm we will suppose is not for ourselves, but is to go to a distance. It may travel in a skep, inverted over the mouth of which canvas or cheese cloth is tied, or we may use what is commonly called a swarm box—that is, a rough case, a convenient size for which would be a foot long, and 10 inches high

and wide. It is not composed wholly of wood, but has two large openings—one in front at the lower part, and the other in the back at top. The lines given indicate a cross section. At *b* perforated zinc is permanently fixed; at *a* zinc is also nailed after the bees have entered. In addition to the hive to receive the swarm we require a flat board, not less than 30 inches each way, and a dome queen cage or little lidless box of some kind. We open the hive as it stands, and search for the queen. The excitement and slight use of smoke cause the bees to gorge while we inspect the combs. The mother is found, and is carefully picked off by the wings and placed beneath the cage, which is stood over the frames upon a piece of card. The hive is now removed to give place to a stool the height of the hive stand, upon which our large board is now placed, while upon it we plant our swarm box or skep, propping the front if the latter with a stone. We take our first comb from the stock, sharply jerking it downwards over the board in front of the swarm box. The bees fall, the older ones at first taking wing, but the younger commence a quick march in; a second comb is brought and treated as the first. The queen cage follows, and we satisfy ourselves that the carefully liberated tenant is safely housed. We add bees from other combs, and if we are pressed for time scoop up those upon the board towards the entrance of the box, using a large address card for the purpose. If we commenced operations in the evening we may leave our box till dark, and then, placing the perforated zinc over the opening, nail up and have ready for transit at once. It is better when honey is being freely gathered to operate in the morning, because at the close of a day's work the limpid nectar is thrown out by the jerking of the combs and somewhat agglutinates the bees; but in the morning the gathering of the previous day has had the advantage of thickening by evaporation during the night.

The hive should now be returned to its stand to receive all those that had been left on the wing at the removal of the box. A few very young bees always drop upon the ground, and would be lost if we neglect to put a stick thence to the alighting board. Although unable to fly they will crawl up this and enter the stock.

If the swarm to be made is to remain with us, and the hive it is to tenant carries a frame of a different size from that of the old hive, we proceed as before, finding the queen and caging her first. This is important, for if we commence work by removing the hive we may be made nervous in feeling that the queen ought at once to be found, and may have in consequence to repeat with emphasis "The more haste the less speed!" The queen secured the hives change places, and about three combs have their bees jerked from them. The remainder of the swarm will be made by the flying bees. The door of the old stock will be contracted, while it should have a bottle of very thin syrup (1 lb. of sugar to a quart of water) given to it, as this will supply the water needful for the grub-raising, and will enable the bees to remain at home to keep at this work. The swarm should also be fed with syrup (3 or 4 lbs. of sugar to a quart of water), and may now be treated precisely as a natural swarm, and will as such receive further notice hereafter.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

HOW I TAKE ARTIFICIAL SWARMS FROM BAR-FRAME HIVES.  
—I remove the crown boards, take a bar hive the same size, and

place it on the top of the one I want to drive; I then blow some smoke in at the mouth of the hive; then drum it (it takes rather longer drumming than a straw hive). I look in at the windows to see when there is a good swarm. There are four windows in my hives. The hives are 16 inches square and 11 inches deep. I then take it off, place it by the side of the parent hive, same as you would the straw. I then put in the ten bars and close it up. I have adopted this plan for three years, and found it answer well.—J. M., *Lincoln.*

#### BITTER HONEY.

IN some places and seasons bees work on Dandelions and Ragweed (*Senecio Jacobæa*) when more eligible honey flowers are scarce, and the honey gathered from the flowers of these plants is dark in colour and disagreeable in taste. It is to be regretted that bees ever touch Ragweed and Dandelion, for the honey gathered from them is worse than useless, as the bees deposit it in cells beside good clear honey. In this way the bad spoils the good and makes it unsightly and unsaleable. Honey gathered from Dandelions and Ragweed is of a dark green colour, and when seen through the cells of white comb appears to be as brown as porter or treacle. A bee-keeper at Partington, about five miles from Bowdon, came to see me ten days ago, when he said that one of his supered hives had swarmed after half filling its super with honey gathered from Dandelions, honey which he described as "black and bitter." About a week ago while walking about in Dunham Park, I called to see the gardens at the Hall, and found that the gardener had six hives full enough for swarming. One had a glass super on it filled with brood and black honey sealed up. Another full hive exhibited its black honey through a glass lid in its crown. The gardener said he had found, about a week before I called, that his bees had been among the Dandelions. He was asked what he would do with the dark-coloured honey. He said it might do "for feeding bees in winter, or be used like Dandelion coffee for people with diseased livers." Though I have long known that bees work on Dandelions and Ragweed in times of scarcity, I have never had in my apiary the dark-coloured honey.—A. PETTIGREW.

#### REVIEW OF BOOK.

*The Stewarton: The Hive for the Busy Man.* By the Rev. E. BARTRUM, M.A., Berkhamstead. 45 pages. London: Longman, Green, & Co., Paternoster Row.

THIS little manual is an honest attempt to popularise the so-called Stewarton hive and system of management. It includes the paper recently read by the author before the British Bee-keeper's Association with the discussion that followed, and several appendices from the well-known pen of "A RENFREWSHIRE BEE-KEEPER," and is illustrated sufficiently to make plain the text. As may be supposed under the circumstances, it is by no means one-sided, like certain other productions of those who have "an axe to grind." True, the skep system is ignored in the discussion, it being taken for granted that the modern hive must be such as to permit the inspection of the cells and the easy manipulation of the combs. Probably the Association may yet bring forward some champion of the skep system whose paper will be looked for with much interest. In this manual the discussion thus mainly turns upon the comparative merits of the octagonal Stewarton and the ordinary rectangular bar-frame hive. Naturally it divides attention between the hive and its management. The advantages of the octagonal form are discussed on the lines of conformity to Nature, and were it not impossible to have uniform and interchangeable frames in such a hive we should at once concede the position. Besides, the form of the hive and its frames (for it seems to be admitted that it must have moveable frames) renders it difficult to make except by experts. It is against it also that it does not admit of using the modern and, we believe, indispensable sections, without at least altering one portion of the hive to the rectangular form.

Under the head of Management we are of course placed under the tuition of the ablest exponent of the system, "A RENFREWSHIRE BEE-KEEPER." We are told to put two prime swarms into the hive at an interval of some days, to tier up or nadir as occasion may require, manipulate slides, &c. We wonder why this system should be admitted, except of course the sides and pegs, by those who discussed the matter as peculiarly the Stewarton system. Did those hives "with legs" have to do with the admission? Ever since we used bar-frame hives we have been in the habit of tiering up or nadiring just as "RENFREWSHIRE" does. Abolish "those legs" and all things are possible.

Our author candidly admits that "for purposes of manipulation

of interchange of frames, for use of the extractor, for the production of marketable sections, the ordinary bar-frame has the decided advantage." But "RENFREWSHIRE" admits nothing of the kind. Neither does he see any advantage in the power given by the bar-frame hive of spreading the brood urged by Messrs. Cowan and Cheshire, nor has he any fear of that imposing tower of ten storeys (figured in the book), on a 6-inch fireclay pedestal toppling over in a gale. Our author is, however, more unbiassed, candidly admits the advantages and disadvantages on either side, and after all does not advise the general adoption of the Stewarton. He has found it suits those who, like himself, have little time to devote to their bees, and "with a minimum of trouble" gives him a "maximum of honey."

We can honestly recommend the perusal of this manual by beekeepers of every school, for outside the matters of debate contained in it there are many facts fitted to stimulate all, and incidental reference to principles that are at the root of all good management.

**BEES POISONED BY THE DIGITALIS PURPUREA, OR FOXGLOVE.**—Last summer I had a large quantity of Foxglove plants, cultivated varieties, and very beautiful in bloom, at the same time a quantity of Canterbury Bells growing near them, and in flower. I was much struck to find that a great number of the working bees were lying dead in the flowers of the Canterbury Bell. Day after day I watched with much interest the movements of the bees, and found that after they had fed for some time on the flowers of the Foxglove they became stupid, and after leaving the Foxglove they went into the flowers of the Canterbury Bell, and, as a rule, died shortly after. Query—Did they die from the poison got in the Foxglove alone, or did it depend on their coming in contact with the flowers of the Canterbury Bell? I could not find any dead bees on any other plant or on the ground near by.—A. PATERSON, M.D., *Fernfield House, Bridge of Allan* (in *British Bee Journal*).

#### TRADE CATALOGUE RECEIVED.

Henry Hope, 55, Lionel Street, Birmingham.—*Book of Designs of Horticultural Buildings.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Book (F. J. J.).**—We know of no book so likely to meet your requirements as Thomson's "Handy Book of the Flower Garden," which is published by Blackwood & Sons, and the price does not exceed half the amount you name.

**Address (S. C. F.).**—The address you require is, 44, Percival Street, Goswell Road, London.

**Gum Water for Pelargoniums (C. D.).**—Place 8 ozs. of gum in 5½ pints of soft water and allow it to remain about two days to dissolve, then strain it through a piece of muslin, and use it from small tins such as ladies use to oil their sewing machines with. The gumming process can be done very quickly with these, as one drop is quite sufficient for a flower.

**Dressing Vine Border (J. A.).**—You may carry out the practice that has been recommended as soon as the fruit is removed from the Vines.

**Benefit Societies (Young Gardener).**—There are no societies that we are aware of that are established with the object of assisting gardeners to obtain situations; but no doubt the members of gardeners' benefit societies assist each other in this respect. There are societies in Leeds and Sheffield, and no doubt a letter addressed to the secretaries would find its destination.

**Rose Leaves Falling (J. T.).**—The leaves suggest that the plants have received a sudden chill, which has arrested the flow of sap. Have you had frost? We presume the injury was apparent before you commenced syringing, and that the application was not too strong. We suspect that the frost which has been so injurious in many districts during last week is the cause of the present condition of the foliage, and that the only cure is more genial weather.

**Variegated Carnation (H. H.).**—We do not know of any Carnation having variegated foliage. We have occasionally seen a plant with the leaves faintly striped with white, but it was usually in a sickly condition and of no value.

**Asparagus (J. F.).**—Your question is almost unanswerable, as so much depends on the nature of the soil and condition of the plants. We have known the produce to vary from 400 to 1000 lbs. from the extent of ground you mention.

**Gooseberries (Idem).**—The following are free-bearing varieties, and afford green fruit early in the season:—Antagonist, Crown Bob, Highlander, Leader, Queen of Trumps, and Whitesmith.

**Tomatoes not Setting (R. G. M.).**—As you have previously succeeded with the same varieties that have now failed, and cannot ascertain the cause of the failure, we fear that we cannot with such data that has been afforded answer your question satisfactorily. We can only suggest that the pollen was not sufficiently dry for dispersion, and the flowers were consequently not fertilised. You will find much information on Tomato culture in Mr. Iggulden's manual, which can be had post free from this office, price 1s. 1d.

**The Austrian Briar (Curate).**—The blooms you have sent are of this extremely bright Rose. It is very hardy, and may be increased by layers; but when plants are established in good soil they usually produce suckers freely, which when detached with roots soon form good flowering plants.

**Raising Single Pyrethrums (G. D.).**—New varieties are raised from seed, and established varieties by cuttings or division of the roots. Cuttings strike readily in gentle heat in the spring, and the roots may be divided in the autumn, yet soon enough for the plants to become established before the winter, otherwise they are best divided just as growth commences in the spring.

**Double Cucumbers (Stephen Castle).**—We have many twin Cucumbers sent to us every year, but not often a specimen showing such a close and continuous union as in the one before us, which is very solid and fine, the weight being 3½ lbs.

**Carrots Withering (G. Davis).**—Your Carrots are infested with the maggot, and in all probability the crop will be nearly worthless. When the plants are in such a state as those you have enclosed there is no remedy. If you sow seed of the Early Horn at the end of the present month, or early in July, on a piece of ground far distant from the present crop, the plants will probably escape injury, and you will have a supply of clean roots in the autumn.

**Potatoes Frozen (J. B., Yorkshire).**—All you can do is to cut off the tops below the parts frozen, and fresh growths will be produced at once. The tubers will in all probability be smaller as well as later, on account of the check the plants have received.

**Sawdust for Rhododendrons (S. P.).**—When Mr. Cuthbert Johnson made his Rhododendron beds he used fresh sawdust mixed in equal proportions with common garden soil, and to this he added a good dressing of bone superphosphate, but we are unable to state in what proportions.

**Begonias Decaying (C. D.).**—You have done quite right in reducing the moisture in the atmosphere, but the soil must be kept moist, and when the pots are filled with roots copious supplies of water are necessary. If the decay does not cease dust the affected parts with finely powdered charcoal. Although you cannot give more ventilation you may perhaps be able to admit air earlier in the morning, and we advise you to do so if possible.

**Northern Spy Apple (Alek).**—You are quite correct. This excellent Apple originated about the year 1840 in the State of New York, on the farm of Oliver Chapin of Bloomfield, near Rochester. It belongs to the Spitzenburgh race, and bears some resemblance to the Esopus Spitzenburgh. Gradually it became a favourite among American orchardists, and in 1843 we find it one of the sorts which were recommended "for trial" at one of the pomological conventions. In 1847 the fruit was sold in New York at 12½ cents, each. It is now largely imported into this country annually.

**Superphosphate of Lime (J. W. Dixon).**—It is more useful as a manure than bones, because it is more soluble in water. If we bury a bone it will remain almost unaltered for years; but if we break it into small pieces it decays much sooner, and if put round the roots of Cabbages will soon make them grow more fine and vigorously. Cabbages, however, are not the only garden vegetables benefited by bone manure, for phosphate of lime is one of the most constant constituents of all plants. Of this phosphate, therefore, the soil is deprived by every crop it bears, and to restore this phosphate to the soil is an object with every cultivator. It was long since shown by chemists that phosphate of lime is the chief ingredient in all bones, and consequently these by degrees have become one of the most extensively used manures. In every 100 lbs. of sheep's bones there are 70 lbs. of phosphate of lime; in 100 lbs. of horses' bones sixty-eight of that phosphate; and in the same quantity of ox bones 55 lbs. As phosphate of lime is insoluble in water, and even bone dust is slow in decaying, it was suggested that by dissolving it in a strong acid, superphosphate of lime, a substance soluble in water, would be formed, and also all the other constituents of the bone be presented to the roots of the crop in a most available form. This process is said to have been first adopted by Mr. Fleming of Berrochan, N.B., in the year 1841. He employed muriatic acid (spirit of salt) to dissolve the bones, but it was subsequently found that sulphuric acid (oil of vitriol) was both cheaper and better.

**Photographs of Leaves (R. M. S.).**—The following process has been recommended for the purpose you name:—At any druggists get a little bichromate of potash. Put this in a 2-oz. bottle of soft water. When the solution becomes saturated—that is, the water has dissolved as much as it will, pour off some of the clear liquid into a shallow dish; on this float a piece of ordinary writing-paper till it is thoroughly and evenly moistened. Let it become nearly dry, in the dark. It should be of a bright yellow. On this put the leaf; under it a piece of soft black cloth and several sheets of paper. Put these between two pieces of glass (all the pieces should be of the same size), and fasten them all together tightly. Expose to a bright sun, placing the leaf so that the rays will fall upon it as nearly perpendicular as possible. In a few minutes it will begin to turn brown, but it requires from half an hour to several hours to produce a perfect print. When it has become dark enough, take it from the frame and put it in clear water, which must be changed every few minutes, till the yellow part becomes perfectly white. Sometimes the venation of the leaves will be quite distinct. By following these directions it is scarcely possible to fail, and a little practice will make perfect. The photographs, if well taken, are very pretty.

**Name of Fruit (J. S.).**—It is not easy to determine the name from a solitary specimen, and we can only say that the fruit resembles a well-kept example of the Northern Greening.

**Names of Plants (J. H. B.).**—The single Orchid flower sent is not sufficient to determine its name with certainty, but it resembles *Oncidium sphacelatum*.

tum. The Fern is *Pteris (Doryopteris) palmata*. (*J. G.*).—1, *Pavia flava*; 2, *Fraxinus Ornus*; 3, *Staphylea pinnata*; 4, *Viburnum prunifolium*. (*A. B.*).—Your plant is *Matricaria inodora flore-pleuo*, and it may be increased by division as growth commences in early spring.

**Removing a Super from a Skep and Clearing off Bees** (*Amateur*).—You can only determine whether your super is ready to take by an examination. If it be of glass this is a simple matter, as the hidden cells of the centre are always finished and sealed before those on the outside. If the combs have been fixed by being built down on to the hive a thin wire must be passed beneath and drawn backwards and forwards gently as it makes its passage, so as to ent rather than tear the comb attachments. In order to clear off bees no plan is more convenient than a Cheshire pin trap, but if you have no book describing this proceed as follows: Take your super to a shady spot, invert it, and place a cloth over its mouth so that no robber bee can enter. Quickly the bees, finding they are prisoners, will come to the light and parade the cloth, which you will turn over at intervals of a quarter of an hour or so. You at each turning put those on the cloth to the outside, while a number waiting to escape will at the same moment take wing and return to the hive. The last two or three may be dealt with by blowing from the mouth down between the combs.

**Uniting Bees** (*Clifton*).—If the driving is intended as a prelude to the destruction of the original stock because of its age, we should strongly recommend that it be not done, for a hive may stand many years and prosper; and the history of this shows that it is doing well, while it will now have the advantage of a young queen in lieu of the old one which left with the first swarm. If you drive unite immediately, as the bees will then be full of honey, which is a prime condition for securing a good reception. The rules for uniting as given in the text books will have to be observed.

#### COVENT GARDEN MARKET.—JUNE 15.

PRICES have generally received a check, business being quieter and goods with difficulty cleared. Some fair samples of outdoor Strawberries have reached us during the week from the southern and south-western districts, but fruit from the home counties is backward.

#### POULTRY AND PIGEON CHRONICLE.

#### AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 477.)

THE one-horse drill which covered in work  $4\frac{1}{2}$  feet was noted last week, but there is a small occupation drill covering a space in work of  $3\frac{1}{2}$  feet only, and we are induced to notice this more especially because it is exactly the width and capacity of a drill which we bought at a factory in Oxford Street, London, in 1845. This was used on our farm for a period of twenty-two years, and was even then in good condition, and had required but very little repair, although it had been in use for drilling every season. Messrs. Reeves & Sons' drill is capable of use for both corn and roots with manure, and all the advantages which can occur in the use of one-horse drills are here present with the lightest possible draught. Being only  $3\frac{1}{2}$  feet wide, it is better

for high lands and hill sides; and when we are speaking of small occupation implements, it is of great consequence to reduce the draught, so that it may come within the power of one horse under all circumstances. This firm also offers a patent corn-sowing apparatus, which in use is attached to any ordinary plough. The advantage of this is, that the seed of corn or pulse is sown at the bottom of the furrow in the act of ploughing, and any quantity of seed can be applied. It is found that in very dry weather, when the Barley or other corn would not vegetate without rain by the usual plan of sowing or drilling on the surface, that when the seed is deposited at the bottom of furrow it is sure to find moisture, and is covered by the loose soil as the next furrow is turned. By this plan we not only insure vegetation but cheat the birds, for they seldom dig after the grain, and as the roots strike into hard firm ground the wireworm or grub seldom do much injury. Again, when the land is heavy, as in the seasons of 1878 and 1879, ploughing and sowing the seed under one operation, it is almost the only safe way of depositing the seed, because if the land is laid accordingly with the plough, it may remain without any harrowing whatever. This applies equally to winter or spring Beans and Peas as to Wheat, for it often happens the weather is too wet for ordinary drilling, and thus the best period of the season is lost. We have seen Beans deposited under a furrow in this way which completely defied the efforts of rooks, and thus the plants are saved.

Machinery of large dimensions and of great importance now requires attention—namely, that supplied by the firm of Clayton and Shuttleworth for the purpose of steam-threshing. Farmers who work a machine for their own use only are advised by the firm to have the single blast threshing machine, so that they may thoroughly mix the sample after threshing on the granary or barn floor, by passing it through a hand-dressing or winnowing machine before sending the sample to market. We cannot, however, recommend this plan of proceeding, for in the case of small occupations it is best to hire the machinery, and with it a staff of competent men not usually to be met with or employed upon small farms; the best and most general purpose machinery for hire in the district can then be selected, and there is no tackle for the combined work of threshing, dressing, and preparing the bulk for market equal to Clayton & Shuttleworth's portable steam-threshing and finishing machinery. It is only on large farms, even where steam is used for tillage and chaff-cutting, that these expensive and large-size machines are kept, and can be used with full advantage; therefore, by hiring the same description of tackle for threshing, the moderate-sized farmers reap the same advantage by hiring as the tenants of the largest occupations obtain by keeping them as part of the working stock of the farm. The machines are made of various sizes, the width of the drum being from 3 feet to 5 feet 6 inches. The sizes of engines required for driving these machines vary also according to the power required. In this matter the size of the machine should be selected in accordance with the work required to be done on the farm besides threshing. In the case of tackle let for hire the engines must or should be adapted to the requirements of the user, and in accordance with the recommendation of the firm who supply the machinery. The firm also fix permanently the patent level indicators to the machine frames, and all running parts are erected in accordance therewith. By this means the machines can even on rough ground be set in a level position for work, thus avoiding undue friction and heating of bearings.

The machines are mounted on wood travelling wheels with improved oil boxes, which greatly add to and facilitate the removal from place to place. The home farmer will see at a glance the importance of easy removal of the machinery, for whether it is on hire or in possession the work will require to be done at the side of the ricks wherever placed, and often at short notice. In

the case of settled fine weather in harvest much corn may be sometimes thrashed in the field without stacking, in which case the straw may be stacked or trussed for sale simultaneously with the thrashing, which is a great saving of time and labour, improving condition of the straw and chaff. Both of these in this country, and particularly in some districts, are valuable according to their condition; but it may be remembered that in America the straw is valued but little, the ears of Wheat being clipped off in the field as the crop is standing and thrashed only for the sake of the grain. In Hungary and other countries the straw in many cases is considered of little use except for fuel to feed the steam engines connected with thrashing out the grain. In the harvest of 1879 we saw farms where the value of the straw was quite equal to that of the grain after being thrashed, even in this country. To return, however, to the construction of the machines, the drums are made of wrought iron, with best tough ash wood beaters armed with the patent rolled steel-ribbed beater plates. The drums are accurately balanced. The drum can be made entirely of iron, but such construction is too rigid. The drum spindles are of steel, very strong, with long bearings, which run on brasses fitted with improved syphon cups. The patent drum protector or safety feed board is fitted to all machines which are made for feeding by hand. This is a necessity imposed by Act of Parliament dated 16th April, 1878. There is now a patent apparatus for self-feeding, which can be attached for use to machines of any size or width. Any of the machines can also be fitted with special drums and apparatus for thrashing Beans, Rape, Mustard, and Turnip seed, as well as the other varieties of corn and seeds. The straw shakers are an important adjunct to this machinery, and are worked by a single crank shaft, the straw being alternately tossed up vertically and moved forward horizontally, which is the best action for separating the grain and chaff from it. If desired, however, double crank shakers are supplied for use in those districts where the straw is required to be sent to market; the shakers are made to deliver it in as straight a condition as possible for trussing off the machine. These machines are also fitted with Barley awner and smutter, consisting of a shaft studded with steel knives, and adjustable beaters, revolving in a cylindrical iron casing. The corn from the awner is passed by an elevator into a second dressing apparatus, consisting of a series of riddles, through which the corn percolates while being acted on by a blast for carrying away the beards, chaff, and smut rubbed off in the awning process. On dropping through the last riddle the corn enters the patent adjustable rotary screen, by which it is sorted into three qualities, the size of the grains of each being determined by the adjustment of the wires of the screen, which is very easily effected. Thus the process of finishing corn, its separation, cleaning, &c., is completed, doing away entirely with the old-fashioned use of the various machines for winnowing, hummelling, screening, &c., so that the separation of Barley from Oats, or any other mixed corn, will be delivered off the machine in a separated and divided sample fit for market. Nor need there be any complaint of the unequal mixture and conditions of corn, because this has always been a matter in the hands of the home farmer; for by his direction any part of a rick or mow of corn may be thrashed separately, so that anything likely to interfere with the regularity of the sample and its condition rests entirely with the farmer himself.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour* may now be employed in preparing and seeding the land for a Turnip crop in the morning, but in the afternoon hay may be stacked in the best possible condition in hot sunny weather. This is an old-fashioned way of proceeding, and we know that let the weather be ever so fine hay is not in good condition until midday. In all cases where a catch crop has been removed the land should not be ploughed unless it can be worked fine and seeded the same day.

*Hand Labour*.—Women will be employed in weeding and cutting

up Thistles and Docks, in fact all kinds of weeds except those which can be pulled up, or the flower buds pulled off by Koldmoor's weeding machine, drawn by one horse, which is the best and only substitute in weeding for hand labour. The men and women too will be required to assist in trimming the Thorn hedges when hindered from more important work, but at all events quickset hedges should be clipped before midsummer, while the young shoots are soft and easily cut up to that time. In trimming banks and borders without quickset plants these should always be cut up whilst green and given to young cattle, breeding sows in the yards, also to milch cows where the milk is sold; and if they get cotton cake at the same time the animals will do well and make better manure than while feeding on roots and cake in the winter months. In those cases where there is a good plant of Hogweed, coarse Grass, Milk Thistles, Parsley, &c., and the first growth cut up in the beginning of May, the second growth will very soon be ready. A man or two should now be employed purposely for cutting green fodder for all the animals of the farm which feed upon it, including the team horses; the horse's labour is then never delayed by the carters being obliged to cut up green fodder for them. Straw should now be drawn and piled up ready for thatching where required, and this work is very conveniently done if showers should hinder other work. We wish also to recommend the practice of teaching some of the farm labourers thatching, in order that the thatching may be done immediately it is required, instead of the bad plan of waiting the time and opportunity for a journeyman thatcher to come and do the work when it suits him and his helpers. We referred last week to matters connected with making and stacking the hay, such as Clover, Saintfoin, &c.; but with regard to park and upland pasture hay it is a different matter altogether, especially if the summer continues dry and the bottom grass very short. In very hot sunshine if the hay is tedded the short undergrowth dries up in a little time, and the horse rake will not touch the short grass, and much is lost altogether, whereas if it is left in swathe the long and short grass dries together in a mass, and can be eared to rick without loss, as it makes very quickly by once turning in swathe and without any tedding. Some men will be employed in hoeing Mangolds, Potatoes, &c.; and where the Mangold seed had been dibbled, or in fact whenever it is very thick in the rows, women should be employed in singling behind hoes, as it can be done with much more regularity by hand than by the hoe. The horse-hoeing should be continued let the weather be ever so dry, as frequent hoeing is found to expedite the growth of the plants. If the Mangold plants make slow growth give the land about 1½ ewt. of nitrate of soda per acre, sown broadcast if the weather should be dry. Cattle Carrots should be freed from weeds immediately they are strong enough to bear the hoe; and in case the Red Intermediate sort forms part of the produce, and there is a probable sale for them in the locality as food for the people, they may be left doubly thick in the lines and pay well for selling. In the event of gaps and loss of plant in the Mangolds, Cabbage, or Kohl Rabi, plants should be planted, but they must be set at the back of the spade, and the land opened deeply to admit strong plants and to reach the moisture of the subsoil; because if the ground is dry, and especially if it is hard, spade-planting is the only successful mode of saving the plants.

*Live Stock*.—Of all the animals of the farm swine are generally much neglected, but like other animals they will pay for care in selecting, and we recommend sorts adapted for producing pork or bacon as the case may be. In fact it is a question of early maturity almost entirely, for those which will make the most growth and yield most weight for age in general give at the same time the best mixed proportions of lean and fat, the importance of which is great either in bacon or pork. The question of size is easily met by early slaughter if pork of light weight is required. The cross-bred animals between the large Yorkshire white and the Berkshire are best adapted for general purposes, these being good breeders as to number and fatten readily. In mating the animals we prefer the Berkshire sow and the white Yorkshire male, but the sow should not be put to the boar until nine or ten months old. Sheep have in many cases been short of grass and green fodder; the weather, however, on the whole having been dry they have not done badly. It is important to notice that the lambs now sent fat to the London market and reared from long-woolled ewes, including Leicesters and Cotswold, do not take so well with the butchers, especially the twin lambs, being hollow and loose in the coat. It is therefore recommended that a horned Dorset or Somerset ram be selected for service in those flocks which are intended to produce lambs for fattening. We have sent horned ewes into the midland counties for the purpose of breeding horned tups for service in the long-woolled flocks, the result of which has been highly approved. In a short time the sale of rams for service in the various down flocks will commence, and for mating with the off-going ewes of the flock we recommend the use of rams of another description from that of the ewes, keeping, however, steadily in view the object of early maturity both as to fattening and weight for age. Thus we would use Oxford down tups with Hampshire down ewes; and Hampshire down tups with Dorset and Somerset cross-bred stock, as well as with horned ewes themselves, at least as regards the off-going part of the flocks.

*FLIES AND HORSES*.—The incessant torment which flies inflict upon horses during such hot weather as we recently endured may not have occurred to the minds of many. Though a minor misery

yet it is so real that I venture to ask you to allow me to describe a plan which I have found thoroughly successful in preventing it altogether, while perfectly harmless. It is simply the application, before harnessing, of a mixture of one part of crude carbolic acid with six or more parts of olive oil. This should be rubbed lightly all over the animal with a rag, and applied more thickly to the interior of the ears and other parts most likely to be attacked. This application may need to be repeated in the course of the day, but while any odour of the acid remains the flies decline to settle, and the horse is completely free from all their annoyance. The nervous irritable state into which some horses get from the attacks of these insects is also not an infrequent cause of accidents, and these, therefore, may also be obviated. Whether the dreaded tsetse of Eastern Africa would also fight shy of similarly anointed animals I cannot say, but it deserves a trial, and if successful would be an incalculable boon. It might also prove obnoxious to mosquitoes.—J. JAMES RIDGE, M.D., *Lond.*—*Enfield* (in the *Daily News*.)

### HAYMAKING.

WITH clear and settled weather a pleasant time is haymaking, for then the work goes on briskly. The grass is mowed, harvested, and carted in four days with the regularity of clockwork, and the stack is a green one, for well-made hay retains most of its colour as well as its sweet odour and nutriment. But when the weather is unsettled and showery it is a critical operation, requiring much watchfulness and caution, or the entire crop may be spoilt. Yet it must be granted that by the exercise of due care, and making the most of every interval of fine weather, much hay might be saved that under looser management is lost. The truth of this assertion was put fully to the test in the wet summer of 1879. I began haying on July 2nd, mowing two acres of grass on that day; but rain set in again before night, and it was a fortnight before the first load of hay was carted. The weather continued very unsettled, gloomy skies and heavy showers predominating so much that the haymaking was not done till the end of August, and yet most of the hay was saved in tolerable condition, being fairly green in colour and possessing a considerable amount of aroma. Very much of it was harvested without sunshine. For example, I find in my diary of that year the following note on July 25th: "Made useful progress with hay, using tedding machine to good purpose. Carried five big waggonloads of hay by working till 7.30. Sky only occasionally visible, and heavy storm clouds all the afternoon, but no rain."

A good barometer is indispensable in haymaking. The success in 1879 was due in no small degree to the fact of each portion of the hay being cut with a rising barometer. That was, and is, a fundamental rule never to be broken with impunity; supplemented by the utmost activity in the subsequent drying and carting during every period of fine weather it goes far to ensure a full supply of good sound fodder for winter. The great difficulty is to thoroughly imbue one's workpeople with the importance of extraordinary exertions in a critical state of weather. I have a lively recollection of my mortification on a certain occasion some four or five years ago, when after a long day among the hay I was called away in the evening, leaving my then bailiff to collect and cart the remaining two loads which we had ready for the rick. He, however, only carted one load, because "the dew was falling fast," and so the other load was left out and quite spoilt by the wet weather which set in that night and continued for a fortnight.

Last year the weather was so dry in April and May, that although Clovers answered well and were a heavy crop, yet the grass crop for hay was both thin and dwarf, which induced not a few farmers to put off the haymaking so long, hoping for showers and a stronger growth, that all the earlier growth was spoilt. Now it is sound practice to mow for hay as soon as the majority of grasses are in flower and before any of them fade, in order to secure the greatest possible amount of nutriment in the hay; for if the grass be suffered to become sere and dried before it is mowed, its nourishing properties have almost all been absorbed by the seeds, which it is well known require them for a full development, becoming full and plump at the expense of the stem and leaves. Acting upon this I was able to make excellent hay, but there was very little of it. Hot showery weather set in soon afterwards, and the aftermath was so abundant that both sheep and cattle improved and fattened unusually fast, and I was able to send several beasts to the butcher off the grass in prime condition before any were put in the yards for winter fattening.

Not only is the aftermath, or second growth of grass, valued for fattening stock, but also for dairy cows. The milk is then at its best, yielding cream so rich that the butter is of a deep yellow and sweetest flavour. It is then that a supply for winter is potted

in crocks, each containing about 30 lbs., and each entirely filled at one operation, and not in layers of different churning, every possible pains being taken to pot it quite fresh, sweet, and free from taint.

Reverting to the haymaking, let me urge upon beginners the importance of harvesting the hay gradually and of carting it before it becomes too dry to eventually develop its full flavour. I have striven to show the importance of briskness and promptitude in haymaking, but unless these desirable qualifications are tempered with prudence and sound judgment they are apt to prove mischievous. A clear knowledge of the right method and degree of dryness is only to be obtained by actual experience, for we must neither expose the hay to a scorching sun till it becomes brittle, nor must we collect it in a flaccid damp condition. There is a mean which we strive to attain, and which causes the hay to undergo a slight fermentation soon after its accumulation on the rick. It is brief in duration and beneficial in action, soon passing off and leaving the hay a dry, sweet, wholesome, aromatic mass of food, such as cattle love and thrive upon.—EDWARD LUCKHURST.

### VARIETIES.

ILLUSTRATED BRITISH BALLADS.—The fifth part of Messrs. Cassell, Petter & Galpin's serial work on the above maintains the high opinion we formed of the first number. The ballads included in the present issue are the Children in the Wood, the Cruel Brother, Cumner Hall, the Demon Lover, John Gilpin, the Doom Well of St. Machon, and the Douglas Tragedy, all suitably illustrated.

— AGRICULTURAL EXPERIMENTS AT WOBURN.—These experiments were instituted last year for the purpose of ascertaining the value of dissolved and undissolved phosphates. The results already obtained show that Wheat cannot be profitably grown on the light soil at Woburn, and probably not on similar sandy soils elsewhere, for a limited number of years, even when the best artificial manures containing both mineral and nitrogenous constituents are applied to the land in much larger proportion than could be done in actual farm practice, on account of the cost of the manures. On strong Wheat land containing a large proportion of good clay, such as that at Rothamsted, Dr. Lawes has grown both Wheat and Barley on the same land continuously for about thirty years.

— HOMING PIGEONS.—Why is it that the Pigeon returns to the spot whence it was taken? It is simply because Nature, in the wonderful variety of her moods, has chosen to give us an example in the Pigeon of an indomitable longing for its home. Compelled to seek its food at a great distance from its nesting-place, this bird of strong flight has had implanted in it also an unerring instinct of direction. Once, therefore, the wild Pigeon used its instinct, and its wondrous endurance on the wing, solely for the purpose of returning as directly and as speedily as possible to its treasures of the nest and pleasures of home. But now in this, as in so many other instances, man has diverted natural gifts to his own ends, and the homing bird serves important purposes in peace and war.

— BEES AND HONEY AT TUNBRIDGE WELLS.—An exhibition of bees, hives, and honey was held in connection with the Bath and West of England Society's Show. This department of the Show was under the management of the British Bee-keepers' Association in conjunction with the West Kent Association. The exhibits of honey, although small in number owing to the early part of the season, were of first-rate quality. Mr. G. Allen of Orpington, Kent, showed twenty-six 2 lbs. sections, and upwards of thirty 1 lb. sections, and gained the first prizes in each class. In the class for 1 lb. sections Mr. Cheshire of Avenue House, Acton, showed a good collection and was awarded second prize. Mr. R. Scott of Blindley Heath, Godstone, showed a good collection of small glass jars of extracted honey. Prizes were offered for observatory and other hives, and collections of bee furniture. The bee tent of the West Kent Association was erected in the ground, and proved a source of much attraction and instruction to the many hundreds of persons who witnessed the several displays of driving, &c., which took place during the several days of the Show. Mr. T. W. Cowan, Mr. J. M. Hooker, and the Rev. G. Raynor acted as Judges; and these gentlemen, together with Mr. Jesse Garratt, the Hon. Secretary of the West Kent Association, and Mr. Huckle, the Assistant Secretary of the British Bee-keepers'

Association, were in constant attendance throughout the Show to give information to the several thousands of inquiring visitors.

— **EXTRAORDINARY TITHES.**—At a recent meeting of the Select Committee appointed by the House of Commons to consider this subject (Mr. Inderwick in the chair), Mr. Bryant of Dunstead Park, Westerham, Kent, said he farmed his own land of about 280 acres, which was laid out in fruit and market gardens. There were 40 acres of Hops and 30 of wood. His property lay in two adjoining parishes. In Westerham he paid an extraordinary tithe of 15s. per acre on Hop land, and nothing on fruit land; in Brasted there was a uniform extraordinary tithe of 14s. per acre on all Hop land and fruit land. The clergyman was the recipient of this extraordinary tithe, and he told witness recently that it was very repugnant to him to receive it. There was an Act passed in the 45th Edward III., in the year 1371, which was the only Act previous to the Tithe Commutation Act of 1836 which dealt with tithes, and that prohibited the levy of these extraordinary tithes. In 1835 and 1836 there was no importation of Hops or fruits of the kind grown in England, and none of vegetables. The home market was entirely fed by the home producer. The importation of Hops since that time had been considerable, and in 1875 it amounted to the value of £1,038,054, and in 1879 to £1,217,938. In 1875 the import of raw fruit of the kind grown in England amounted to £986,248, and it had increased to £1,746,936 in 1879. Onion imports were in 1879, £450,019; Potatoes in 1875, £1,070,976, and in 1879 £2,696,885. The effect of the extraordinary tithe was to strangle this industry in England; the tithe had to be paid whether any profit was made out of the market gardens or not. There was a gentleman at St. Paul's Cray who had 3000 acres in Hops and fruit, and had to pay £900 a year in extraordinary tithes. Witness had introduced upon his farm the undercropping of fruit plantations with market gardens; the land was previously in Turnips and Wheat. On being asked by the Chairman to propose a remedy for this extraordinary tithe, Mr. Bryant replied, "Total extinction, it ought never to have been imposed." We think most people will agree with him.

— **WHEAT PRODUCTION AND TRANSPORTATION.**—The "New York Tribune" states the average cost of producing Wheat in the Far West is estimated at 84 cents per bushel, and a vast quantity of Wheat is raised in this country at a lower cost. The average cost of transportation to Liverpool, exclusive of  $3\frac{1}{2}$  cents for hauling in this country, and  $6\frac{1}{4}$  cents for Liverpool charges, has been put at 50 cents per bushel—viz., 20 cents from the farm to Chicago,  $15\frac{1}{2}$  cents thence to New York, and  $14\frac{1}{2}$  cents from New York to Liverpool. The charges now, though navigation is not yet open, are 15 cents from St. Paul to Chicago, 18 cents from Chicago to New York, and less than 10 cents from New York to Liverpool. Even this low rate will be greatly reduced whenever it becomes necessary in order to secure a market for the surplus grain of the Far West. Indeed, even now grain is being removed from St. Louis and St. Paul to Liverpool at less cost than from the Mississippi River to New York. A single tug has just taken 1900 tons of grain from St. Louis in barges on the way to New Orleans. With an ordinary stage of water the charge is said to be 5 cents a bushel from St. Louis, and 15 cents from St. Paul. Much more than half the grain exported crosses the Mississippi River. The actual cost of transporting by barges is said to be little more than half the rates now charged; so that, if it were necessary, in order to secure a market abroad, more than a hundred million bushels of grain could be moved down the river for less than 5 cents per bushel from St. Louis. Hitherto lack of facilities and of shipping at New Orleans has restricted the movement; but charters have actually been made in this city within the past week for vessels to take grain from New Orleans to Liverpool at 6d., or 12 cents per bushel. If surplus grain is moved even now for not more than 17 cents per bushel from St. Louis to Liverpool, whereas the present cost by rail from St. Louis to New York is about 20 cents, the British farmer has not yet felt the full force of American competition. From St. Paul to Liverpool the present cost is 27 cents, whereas the rate by rail from St. Paul to New York is 33 cents per bushel. The river route, though not enough used now to influence railroad rates materially, as these quotations show, is liable to be very largely used when-

ever the possibility of selling two hundred million bushels of Wheat from the north-west depends upon the cost of transportation thence to Liverpool. Then it will doubtless be found that grain can be moved from Minnesota to Liverpool for less than half the cost of transportation allowed by the British Commission. In short, the British farmer, who acknowledged that he could not hope to compete with American grain costing in England less than 1.43 dol. per bushel, may find that he is obliged to sell his own grain at less than 1.18 dol. per bushel in order to keep the home market for himself. It is not necessary to say that one season of such competition would put a stop to Wheat-growing on a great many farms in England.

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 454.)

#### FRESH BLOOD.

As will have been manifest from what has been already written, it ought to be several years from the first starting of a strain before it is necessary to introduce fresh blood; but be the years few or many, the time is sure to come when the step can no longer be avoided. This being so, the prudent fancier will do well to anticipate the necessity, and make such a provision for his needs that the fresh cross shall be as little harmful as possible.

The introduction of absolutely new blood into a strain can be postponed in some cases by an expedient which is not always practicable. A colony may be established in some friendly yard as distant as possible from the parent yard, and a sub-strain there formed from which the original strain may be recruited. We say "as distant as possible" advisedly, for climate, soil, elevation, &c., have an undoubted effect upon the constitutions of the birds, and a sub-strain established in a locality which is essentially different in its natural characteristics from the home yard will become in the course of a few years so affected by its surroundings as to be for practical purposes almost a distinct strain. Birds from such a sub-strain may be used with great advantage in the home yard, and their use will be found to produce a considerable increase in the stamina of the parent stock.

It is not everyone, however, who can adopt this plan, and even if adopted it can only postpone the day when absolutely fresh blood has to be introduced. This must be done gradually, and it is for this reason that preparation should be made for the necessity before it actually arises.

Bearing in mind that a cross between totally unrelated birds generally results in the production of progeny which are worthless in fancy points, it is apparent that it would be by no means prudent to introduce a fresh cross at once into the breeding yards. To purchase a cockerel from a foreign strain and mate him up with several of the best hens would, except in a very large yard, be a useless waste of a season's chances of obtaining valuable chickens. It is quite sufficient for the purpose of recruiting the energies of a strain that the birds crossed into it should have in them one-half fresh blood. The fresh blood can therefore most easily be introduced by obtaining a hen or pullet from a strange yard, mating her with one of the best cocks of the home strain, and selecting from amongst the chickens bred from this cross those most suitable for supplying the necessary fresh blood. The birds so selected can, even though themselves defective in points, be relied upon to do little injury to the strain and to produce a good proportion of valuable chickens. If a yard be available for the purpose the purchased hen may be in-bred to, and a supply of comparatively fresh blood be thus obtained for future use.

If for any reason it be thought more desirable that a cockerel should be purchased instead of a hen or pullet, the only disadvantage will be the practical loss of a breeding yard for the season, and it may be well to let the hens or pullets mated with him represent all the original elements of the strain as fully as possible. In this way some unknown relationship may be hit upon and some much better chickens obtained than would otherwise have been the case.

Where space is very limited the easiest way of obtaining fresh blood is by purchase from some friendly fancier, to whom a bird has formerly been sold, of a cockerel descended from the bird so sold, but having a large proportion of other blood in his veins. This plan may indeed be adopted under any circumstances where

it can be clearly ascertained how the birds are bred; but that is a matter as to which breeders do not always care to be explicit, and conscious ignorance is preferable to supposed knowledge.

In choosing a bird to cross into a strain regard should be had to the points, if any, in which the strain is deficient. The bird selected should be of extra merit in such points, and, if it is not intended to in-breed to the new purchase, exaggerated development in the points will be advantageous. A knowledge of the family from which the selected bird is descended is also of importance for reasons already noted, and where practicable that family should be (except as regard defects) as much as possible of the same type as the breeder's own strain. Where the breed kept is one in which it is customary to mate up separate yards for breeding cockerels and pullets, and that plan is not followed by the intending purchaser, extra care is necessary in ascertaining the family history of the new purchase. We have known cases in which most unlooked-for peculiarities have turned up in cockerels hatched from birds which were only intended for pullet-breeding and *vice versa*, and such peculiarities are generally very difficult to breed out. In addition to cases in which the introduction of fresh blood becomes necessary to counteract the ill effects of in-breeding, there are also cases in which in consequence of some original deficiency in the strain fresh blood has to be infused. These cases require special mention, inasmuch as the existence of such a defect generally necessitates the crossing-in of the new blood—intended to counteract it—more than once, and in fact leads rather to the formation of a new strain than to the mere introduction of fresh blood into a strain already formed. In such circumstances the new blood must be of special excellence in the point in which the old strain was defective, and must also be of such general excellence as to be fit to form the foundation of a strain.

The considerations which are applied to the introduction of fresh blood to the poultry yard are generally applicable to the Pigeon loft, with the exception that as Pigeons are monogamous it is immaterial as regards space whether a cock or hen be used to infuse the necessary fresh blood. The choice need, therefore, only be affected by regard to the preponderating influence of the cock or hen in reference to the points in the strain which most require amendment. If the weak points be those in which the male parent has most influence, a cock should be selected of special merit in these points, and *vice versa*. The last-named consideration also deserves attention where fresh blood is introduced into the poultry yard to counteract defects of the strain.

(To be continued.)

### POULTRY NOTES.

THOSE not well acquainted with the so-called "non-sitting" varieties of poultry very frequently are alarmed if a Spanish, Hamburgh, or Polish hen by chance shows a desire to incubate, fearing it an indication that she is not of a well-bred race. It may be well at this time of year to inform them that such cases are by no means uncommon, that they do not prove any impurity of breed, and that as a rule such hens turn out excellent sitters and mothers. If we remember rightly Mrs. Arbuthnot, a very accurate authority on poultry lore, gives her experience in her book that Hamburgs which enjoy a wide range frequently sit. Our observation leads us to agree entirely with her, for our Golden-pencils, which range at large through woods, sit year after year, and rear immense broods, though generally a little late in the season. A single Silver-pencilled hen too of high pedigree, which we possess, has both last year and this year done the same. None are more careful and faithful mothers; they are peculiarly adapted to Bantams and Pheasants.—C.

### TOY PIGEONS.

(ORIENTAL FRILLED PIGEONS.)

THE importations from the East which have brought us Turbiteens have also brought us many other frilled Pigeons of great beauty and delicate colours and markings. Like Turbiteens they are all frilled on the breast, have feathered hocks and legs, and, like Turbiteens, they may either be plain-headed or point-crested. Their general form and points of form, too, are the same as those of Turbiteens, but there is a difference in their markings; in fact there are, so to speak, two distinct families of them. Some, Turbit-like, have white for their ground and a shield of variegated colour on the wing, where Turbits have one whole colour; their tails are coloured too, as those of some English Turbits seem to have been of old; others are parti-coloured all over, and so more like Owls.

The principal sub-varieties of the former class are called Satinettes,

Brunettes, Bluettes, and Silverettes; of the latter class Blondinettes are the only very distinctive type. It must be remembered that there is no generic difference between the different sub-varieties of the Satinette tribe, as there is no generic difference between Red, Yellow, and Black Jacobins or Turbits. The difference is chiefly one of the degree of shades, the production of which must be studied by a fancier who makes any attempt at scientific breeding. The colour of the shoulder or shield of Satinettes is very peculiar; it is a mixture of black, white, and a kind of pink; these shades are intermixed in different ways. The marking of the tail in good specimens is very accurate and distinctive, each feather having a round white spot on a darker ground at the end of it. The Brunette is simply a lighter Satinette, to which it has much the same relation that a Yellow Turbit has to a Red. Bluettes and Silverettes have bars on their wings, and so correspond with Blue and Silver Turbits. The colour of their shoulders and tails is blue and silver respectively, and their bars are double—i.e., two distinct lines of white and brown, like those of Blue "Shields" in their younger stage, though we believe in the case of Silverettes brown should be absent from the wing, and the bars should be black and white. Blondinettes, which, as we have said, are coloured all over, are very varied in the degree of their shades. Their general colour is a mixture of blue and the pink of Satinettes. The head, neck, and body show the blue most clearly, while the pink marking is most distinctly seen on the shoulders. Their flight feathers are generally laced with black, and the tail marking is very distinct.

It is in vain to search any of the old works on Pigeons for information on these varieties. They were not known to our ancestors. All the more interesting is it for young fanciers to master for themselves their peculiarities, and the effects of various unions of the different sub-varieties. We are too apt in these days to trust entirely to books and to the labours of others. A little observation would in this case be well worth the while of any intelligent lover of Pigeons. That the Eastern fanciers must have spent much time in producing birds so unlike in colour to the original wild Pigeon, and which accurately reproduce markings so peculiar as those of the tails of these birds, is without doubt. Our observation of them may be much helped by a visit to the autumn show at Birmingham. Special classes are now made there for oriental frilled Pigeons, and it is a real treat to see the beautiful collections which Mr. Ludlow and other of their admirers there exhibit. We do not profess ourselves to have had any large experience in them, but those which we have tried have proved very hardy when kept in a natural way and chiefly at liberty. We believe that other sub-varieties may still be imported; indeed, we have seen several, but do not venture to assert that they have been bred long enough to one distinctive type to reproduce their like. We once much admired at Birmingham a "Blue Vizor." His body was white, his wings blue with white bars, and his tail blue with white markings; but his distinctive feature was a blue head, as if a coloured veil had been drawn over it. Such rarities, however, can only be acquired by fanciers who can afford to pay for them.—C.

### REMARKS.

5th.—Dull and overcast; rain commenced 0.30 P.M., continued steadily rest of the day.  
6th.—Wet morning; afternoon fine, with some sunshine and thunder at intervals; thunderstorm in N.W. 6.40 to 7 P.M.; wet evening.  
7th.—Cooler, with slight showers during the day; hail at 11 A.M.; fine evening.  
8th.—Cool, fine generally; slight showers in forenoon.  
9th.—Cold; fair on the whole; windy.  
10th.—Calm, fair, cloudy, and cool.  
11th.—Fine morning; hazy and thick in afternoon; fair evening.

A most remarkable fall of temperature followed the heat of the week ending with June 4th. The fall has affected all the elements of temperature, but most markedly the average maximum temperature in shade, which in last week was 78° 5', and this week only 61° 6', a fall of 16° 9'—a rare if not unprecedented fall.—G. J. SYMONS.

### THE ROYAL HORTICULTURAL SOCIETY.

IN another page we publish the full text of the judgment of Mr. Justice Fry in the action of the Royal Commissioners of the Exhibition of 1851, as landlords of the gardens in the occupation of the above Society, on the alleged grounds of non-payment of rent. The differences that have existed between the Commissioners and the Society have probably never been made so clear to the horticultural public as they are now.

The question at issue has, perhaps not generally, yet to a very great extent, been regarded as a simple difference between landlord and tenant, as if the case were one of ordinary private property and where the tenant's right of occupation rested solely on his actual payment of rent. Judged, as the Society has undoubtedly been judged on this basis, the result has been that to a not inconsiderable extent it has suffered from an alienation of public sympathy and has been deprived of the support which it would otherwise have had.

Whatever may be said against the rights of property, the sense of justice is so deeply engraven on the public mind of this country, that a man or body of men refusing to fulfil engagements that have been entered into is not likely to enjoy public confidence. If by imprudence, or, indeed, from almost any cause, rent is not forthcoming when it is due, the defaulter pays the penalty imposed by the circumstances, and the landlord exercises his undoubted right to recover possession of his property. Although the tenant under certain conditions may receive a measure of sympathy, it is not usually of a substantial character, and when once the word "rent failure" attaches to a man, company, or society, public support is immediately estranged. That a feeling of this kind, more or less appreciable, has been entertained in respect of the Royal Horticultural Society is certain; but it is one of the most hopeful signs of the future, notwithstanding the peculiar position of the Society—with past dissensions still exerting a baleful influence, with difficulties impeding its progress, with the then pending litigation engendering a feeling of uncertainty as regards the future—that such steady and in some instances such generous support should have been accorded it during the past few years. This support could not have been conferred had not the true position of the Society been understood, and had not the Council carried out the objects for which it was established in a loyal, legitimate, and honourable manner.

A careful perusal of the very able and singularly lucid digest of the whole case by the Judge, will show most conclusively that the relative positions of the Commissioners

and the Society are essentially different from those that ordinarily exist between landlord and tenant. The payment of what is called rent is not the first and paramount duty of the Society. Other stipulated conditions have to be fulfilled, and not till these have been complied with can payment of a sum be demanded by the Commissioners, and before the demand can be tenable it is incumbent that the precise sum that is due be ascertained. That this was not done was certainly not the fault of the Society, for the Commissioners were formally invited by the Council to summon the Expenses Committee, but the request was not complied with. In this they erred, so far as regards sustaining their position and demand, and the Society legally maintains its ground; and in another important respect it maintains it morally also, and this as regards their defence of the interests of the debenture holders.

It may be said that the recent action was decided on a technical point—the non-fulfilment of a certain stipulation that did not affect the real merits of that part of the case in which the interests of the debenture holders were involved. This is, to say the least, taking a very advanced view of the case. The real position of the question is this—One given and essential point was abundantly sufficient in the estimation of the Judge for determining the question at issue, and it was unnecessary to enter elaborately into any subsidiary issues, however important these might be. Yet, sufficient was said incidentally on the injustice to which the debenture holders would have been subjected if they had been deprived of their security in the summary manner proposed. Instead of their position being weakened, it has been greatly and justly strengthened and fortified, and in substance as well as in form the case was won by the Society.

Here the litigation ends, and it would have been better if it had not been begun. The Commissioners, however, felt it their duty to put the law in operation, and the Society, considering their relations with the debenture holders, had no choice but to defend the action. Under the circumstances, even if the case had terminated differently, it is not conceivable that the horticultural public would have disapproved of the action that was determined upon by the Council.

But to the future. Cannot any differences that may arise between the Commissioners and the Society be settled by mutual arrangement, and in an amicable manner, consistently with justice being done to all parties, so as to improve the property of the one without injuring the interests of the other? This is what we consider could be done and should be done; and we further think it might be done if united action were taken, and an earnest endeavour made to settle such differences in a satisfactory and equitable manner.

The position of the Society stands thus: It was established to promote and support an important industry—the improvement and promotion of scientific and practical horticulture. To this end such resources that may be placed at the command of the Council will be applied. The extent of the work to be done depends wholly on the support that is received. For some time past uncertainty has prevailed, an uncertainty that could not be otherwise than enervating. Yet notwithstanding there has been a steady accession of new Fellows; and now that firmer ground will be felt, and safety is secured for some time to come, it may be reasonably expected that a larger measure of support will be accorded.

It remains now for all who are interested in the Society to rally round the Council and assist in restoring the former income, so as to enable it to fulfil all its engagements, and not the least of these its advancement of horticulture.

### CHOICE VEGETABLES.

**BROCCOLI.**—The severity of last winter made sad havoc with the crops; many, especially of the early varieties, being totally killed. Penzance suffered most, and evidently is not suitable for cold northerly localities. Veitch's Spring White and Cooling's Matchless were much injured, and we had not any really good heads until Leamington was ready on the 6th of May. Not any of Leamington, Lauder's Goshen, nor Model were killed, and they headed excellently; Goshen continuing to June 10th, and Model to June 17th. Model is good in every respect, the plant being very dwarf and sturdy, having little stem for the frost to affect, and the foliage thoroughly protects the heads, rendering them quite white, added to which they are very compact. On a north border this variety affords valuable heads until Cauliflowers are ready. It is the model of what a Broccoli should be, and is a decided acquisition.

**CAULIFLOWERS.**—These have had a hard time of it, there being few crops in gardens that are not tried by cold 3° below zero. In an ordinary season plants winter fairly well with the protection of a wall, and in frames and under handlights, but many plants succumbed in the two latter. The hardiest were Walcheren, next Early London, and the others much alike. What Model is in Broccoli, Veitch's Early Forcing promises to be in Cauliflowers. It has short stems, comparatively small leaves, and the heads are not too large, but just suitable for table. It comes in fully ten days in advance of Erfurt Mammoth and a fortnight before Early London, and will become as great a favourite for early work as Autumn Giant is for late use.

**LETTUCE.**—Not any of the outdoor plants survived the winter, but those with no more protection than the lights survived in frames. Paris Market came in first, closely followed by All the Year Round, both of which are closely hearting sorts, and Stanstead Park gave its larger but not so close heads in an immediate succession. In Cos varieties, after trying many I find none to equal for standing the winter in frames the Bath or Brown Sugarloaf, which forms fine heads and lasts long enough to meet the first sowings of Early Paris Market outdoors, which comes in ten days in advance of any other.

**CABBAGES.**—Ellam's Dwarf Early Spring is another model, the plant dwarf and compact, and has stood the winter well, while many others had their ranks much thinned. It heads quickly, has few outside leaves, therefore little waste, and is not only earlier than any, but is of excellent quality. Hill's Incomparable stood the winter well; Wheeler's Imperial, Nonpareil Improved, and Cocoa Nut much cut and destroyed by the cold. I think the latter one of the best flavoured, quite equal to Little Pixie.

**TURNIPS.**—What a season for fly! Many have had several successional sowings of Turnips, and the plants are eaten. If attacked in time with quicklime applied early in the morning and the practice is continued it saves the Turnips. I had a strong fight with the insects, but conquered; and, what is more, Turnips like lime and wood ashes. Early Purple-top Munich came into use ten days in advance of Early Snowball, which last is the best flavoured of any, being very sweet and tender. Six-weeks is also excellent, and for general crop Veitch's Red Globe is fine both in shape and flavour.—G. ABBEY.

### COLUMBINES.

YOUR woodcut and description of *Aquilegia Stuartii* suggest a few notes on this beautiful class of plants. A statement was lately made in the editorial notes of a gardening journal that no hybrid Columbine could be worth growing. The remark showed more botanical zeal for the purity of species than horticultural appreciation of beautiful flowers, for many of the finest Columbines to be seen in gardens are undoubtedly hybrids: but it is a most important quality in a hybrid that it should be capable of reproducing itself true from seed, and many hybrid Columbines are deficient in this. About twenty years ago I bought a packet of Columbine seed under the name of *Aquilegia fragrans*. None of the produce was at all like the true fragrans, which I have never been able to get, but one of them corresponded to your description of *A. Stuartii*, and flowered well in my garden at Eton for three or four years, when, because I could not obtain it true from seed, I attempted to divide it, and lost it. I have not seen the same hybrid again till this spring, when about the end of May I recognised my old friend amongst some cut flowers in a house in

London. I asked the owner to take me to his garden, situated amongst the Surrey hills, a few miles south of Dorking, where a splendid plant of it was growing, bearing tall branching stems and large pendulous flowers, expanding fully 3½ inches, the sepals being rich blue, somewhat darker than the blue of *A. glandulosa*, and the corolla white with a tinge of blue in the throat. There were also some seedlings, sown when the seed ripened last year, which were already flowering, and were true in all their characters. The plant had been bought of Mr. Ivery, nurseryman of Dorking, as *A. Witmanniana*. I considered it as a hybrid between *A. glandulosa* and *A. vulgaris*, but from what is said of *A. Stuartii* I now think it probably may have been from seed of the small-flowered Columbine generally sold as *A. Witmanniana* crossed with *A. glandulosa*; but probably Mr. Ivery can tell us its history. A similar flower, but of a lighter blue, was sent to me lately in a box of Columbine flowers by Mr. William Thompson of Ipswich. He considered it a cross between *A. glandulosa* and *A. vulgaris*.

With regard to *A. glandulosa*, which you call a shy flowerer; it certainly is so generally in England, but as we get northwards the character and habit of the plant improves, until they reach their climax in the nurseries of Mr. Grigor of Forres, where it produces abundance of flowers and has a branching habit. In most parts of Scotland it flowers much better than in England. I had a fine plant full of flowers sent to me this spring from a private garden in Midlothian.

I am told that to hybridise Columbines successfully it is necessary to isolate the parent plants under glass, and to exclude bees and flies. In my garden, which is full of Columbines of different species, I seldom find a flower which I can be sure is a natural hybrid, and my attempts to hybridise selected flowers in the open air have not hitherto been successful; but I have not yet found any difficulty in keeping species true. The strange varieties of *A. vulgaris*, both in form and colour, are endless, and one can never foretell what the seed will bring; but *A. cærulea*, *A. flavescens*, *A. glandulosa*, *A. chrysantha*, and *A. Skinneri* from seed show all their true characters. The last-named, indeed, has no excuse for hybridising, as it seldom flowers with me till July, when all other Columbines are over.—C. WOLLEY DOD.

### YORK FLORAL FÊTE.

JUNE 15TH, 16TH, AND 17TH.

ANNUALLY for twenty-three years the old city of York has produced exhibitions of plants, flowers, and fruit that have been excelled by few in England; and again in the present year a most satisfactory Show has been held, constituting, in the opinion of many old visitors and exhibitors, one of the finest since the commencement of the Society. Not only were most of the important classes well filled, but the health and floriferousness of the plants contributed a general neatness and brightness to the display that was very pleasing. As usual there was a central circular marquee from which radiated four long tents, one being devoted to Pelargoniums, another to Roses, a third to fruits and cut flowers, and the fourth to stove and greenhouse plants, while an additional tent was occupied with the groups. In the central marquee were the large specimen plants and exotic Ferns, the former being an especial attraction owing to their fine condition. They formed an imposing group, and were greatly admired both by horticulturists and general visitors. Pelargoniums as usual constituted a very important feature, and were, considering the season, excellent both in vigour and in the size, form, and colour of the flowers. Roses were represented by numerous collections, but there was a somewhat too noticeable roughness in the plants, though the foliage and growth were strong and clean. The other sections of the Exhibition were similar to previous occasions; and though, perhaps, in some classes the competition has been more keen at other times, still, taking the Show as a whole, there was very little cause for dissatisfaction upon that score. Indeed there were very few shortcomings in the display, which was alike creditable to the exhibitors and the managers, well maintaining the fame of York as regards horticultural productions.

**PELARGONIUMS.**—From year to year there is little variation in the extent and beauty of the display of this popular and handsome plant; and though the specimens become familiar to us, yet they are always worthy of the admiration they irresistibly awaken. Nearly all sections of the genus are represented; but the Show, Zonal, Tricolor, and Bronze varieties are the chief features, the Fancy varieties being usually represented by comparatively few collections. The competition in most of the above, with the exception of the latter class, was close, and in consequence the Judges experience much difficulty in making the awards in some instances, and rarely have there been so many equal prizes adjudged as on this occasion—a sufficient indication of the comparative quality of the exhibits.

**Show Varieties.**—Three classes were devoted to these. For twelve specimens Messrs. Lazenby & Son, York, secured the principal prize for vigorous well grown and trained examples, not too formal, and yet neat and symmetrical. The varieties have been enumerated in several previous reports; but it may be remarked that Claribel,

Countess, Duchess of Edinburgh, and Prince Leopold were unusually fine, the flowers large and abundant, the trusses of good size and compact. Mr. C. Rylance, Aughton, the only other exhibitor in the class, was placed second with a meritorious collection including Queen Bess and Triomphe de St. Mande in excellent condition. In the amateurs' class for six specimens Mr. Eastwood, gardener to F. W. Tetley, Esq., Leeds, was first with plants of moderate size bearing large flowers, Mr. Gowthorpe, gardener to Miss Steward, taking the second position; and equal thirds were awarded to Mr. J. R. McIntosh, gardener to J. T. Hingston, Esq.; H. Wright, gardener to G. Talbot, Esq.; and Mr. H. May. Three Show varieties were contributed by Messrs. Gowthorpe, Simpson, and Eastwood.

**Fancy Varieties.**—Though these were not numerous they were of fair quality, but they have, perhaps, been shown in better form. Mr. Rylance was first with six specimens even and well flowered, the varieties Sarah Turner and Roi des Fantaisies being especially noteworthy. Mr. Eastwood was second with smaller examples but neat. Three plants were shown by Messrs. Eastwood and McIntosh, who were awarded the first and second prizes.

**Zonal Varieties.**—Two classes were appropriated to this section. For twelve Mr. McIntosh carried off chief honours with well-flowered but rather formally trained specimens. Marvellous, R. C. Clifton, Crimson King, and White Vesuvius were the best. Mr. R. Simpson secured the second position for healthy examples, Clipper being particularly fine. Mr. Eastwood was third with rather rough but bright plants, Mr. Hockney being fourth, and an extra prize was adjudged to Messrs. C. Lazenby & Son. Collections of six were staged by Messrs. T. Simpson, Wright, McIntosh, Hockney, and McIndoe, gardener to J. W. Pease, Esq., Hutton Hall, Guisborough, who secured the prizes for fair specimens mostly flowering freely. Double-flowered varieties were not shown in first-rate condition, but a few good specimens were contributed by Mrs. E. Jackson; Mr. C. Clarke, gardener to Miss Wharton; Mr. Eastwood; and Mr. R. Simpson, who were the principal prizetakers.

**Bronze Varieties.**—Very fine specimens were staged in the classes devoted to these plants, the dark zones being well developed, the foliage vigorous, and the plants of good size. Mrs. E. Jackson was first with six evenly trained, strong, well-coloured specimens, Marshal MacMahon, Vicar of Wakefield, Waltham Bronze, Black Douglas, and W. E. Gumbleton being the chief of the varieties. Mr. Clarke followed closely, Earl Rosslyn being finely represented in his collection. Mr. R. Simpson was third, his best plant being Earl of Beaconsfield, a distinct and striking variety, having an extremely dark zone. Mr. Hockney was placed fourth.

**Tricolor Varieties.**—These also were shown in satisfactory condition, the foliage being very highly coloured. Mrs. E. Jackson had the premier collection, comprising Mrs. Clutton, Lady Catherine, Empress Eugénie, and Flambeau, all good. Messrs. McIntosh, R. Simpson, and Simpson & Sons secured the remaining prizes in that class for similar plants. The best three were from A. J. Cholmondeley, Esq., who had Prince of Wales, William Sandy, and Sophia Dumasque in fine condition; Mrs. Jackson, the Rev. G. E. Gardner, and Mr. H. Banks taking the other prizes for neat and well-grown plants.

**STOVE AND GREENHOUSE PLANTS.**—The most valuable prizes offered by the Society were those for a group of ten stove and greenhouse plants, open to all exhibitors, in which £20, £14, and £8 were offered as first, second, and third prizes. Three competitors appeared, and their contributions as arranged in the central tent not only produced a beautiful display, but they also excited very much interest on the part of the horticultural exhibitors, as two of the collections were extremely close in merit. The much-coveted first prize was secured by Mr. Letts, gardener to the Earl of Zetland, Upleatham, who staged handsome specimens that would not have been easily surpassed. The foliage plants were uncommonly fine, both large and healthy; *Encephalartos*, *Dasylium acrotrichum*, *Cycas circinalis*, *Gleichenia rupestris glaucescens*, *Croton Weismanni*, and *Croton Johannis* being very attractive. The last-named was in superb condition; it was 5 or 6 feet high, and one of the most brightly coloured specimens we have seen. The flowering plants were *Allamanda Hendersoni*, 5 feet in diameter, of globular form, and bearing abundant large flowers; *Ixora coccinea*, with fine trusses of flowers; *Stephanotis floribunda*, very neat; *Erica insignis*, even and well-flowered; *Dracophyllum gracile*, *Clerodendron Balfourianum*, and *Anthurium Schertzerianum*. Mr. Tudgey, gardener to J. F. G. Williams, Esq., Worcester, was placed second, but his plants so nearly balanced those of the preceding collection that many considered they were entitled to equal awards. They were all in excellent condition; *Pritchardia grandis*, *Erica Cavendishiana*, *E. ventricosa*, *coccinea*, and *magnifica*, *Latania borbonica*, *Croton Johannis*, and *Anthurium Schertzerianum* being the best, and have been previously mentioned in the reports of the Royal Horticultural and Botanic Society's Shows. Mrs. Cole & Son were awarded an equal second prize for fine plants, but there was much greater difference between the quality of the last two than between the first and second. *Croton Weismanni*, *Cycas revoluta*, *Latania borbonica*, and *Dracophyllum gracile* were the chief specimens. In the smaller classes healthy plants were contributed, but they do not need special description. Mr. Letts; Mr. Noble, gardener to T. Fry, Esq., Darlington; Mr. Berry, gardener to W. Dove, Esq., York; Mr. Wright; and Mr. Rolleston, gardener to W. Bateman, Esq., Harrogate, were the chief exhibitors.

**Roses.**—A pretty display of Roses in pots was contained in a large marquee, the flowers being fairly abundant, and the distinctive colours well developed; the blooms, too, were of fair quality in the chief collections. For six varieties Messrs. Pybus & Son were first with neat examples of *Boule de Neige*, *Madame Lacharme*, and *Madame Guillot* among others; Messrs. Jackson & Co. and H. May taking the other prizes for healthy but slightly rougher examples. The same exhibitors held similar positions with nine specimens, good varieties being staged in each collection. In the class for fifteen specimens Messrs. Jackson & Co. were placed first, followed by Messrs. H. May and Pybus & Son, all contributing fairly satisfactory plants.

**Orchids.**—York does not usually produce a large exhibition of Orchids, though fair specimens are generally included in the leading collections. Dr. Ainsworth, Manchester, was adjudged the chief honours for six specimens including *Saccolabium premorsum* with six spikes, *Phalænopsis grandiflora*, *Vanda suavis*, *Odontoglossum vexillarium*, *Aerides Schrederi*, mostly what are termed "made-up plants," but all in vigorous health. Mr. Dodgson followed with smaller but neat plants; Mr. Hayward, gardener to Captain Hincks, being third for similar plants. In the other classes there was nothing very remarkable, the above-named exhibitors securing the chief prizes.

**Fine-Foliage Plants.**—Some handsome specimens were staged in the two classes for "ornamental, fine-foliage, or variegated plants." Mr. Tudgey was deservedly placed first with eight, which included *Cycas revoluta*, *Croton Andreanus*, *Pritchardia pacifica*, *Croton Queen Victoria*, and *Cocos Weddelliana*, which have been previously seen at Regent's Park and elsewhere this season, and therefore need no comment. T. Fry, Esq., Darlington, was a good second, having *Croton Veitchii*, *Cycas revoluta*, *C. circinalis*, and *Anthurium crystallinum*, large and healthy. Mr. McIntyre, gardener to Mrs. Pease, Darlington, took the third position with vigorous plants. The best four specimens were contributed by Mr. Winterbourne, Mr. Berry following, and single specimens were staged by Messrs. Talbot, Tudgey, and Tetley.

**Exotic Ferns.**—For eight specimens of exotic Ferns Mr. Tudgey obtained chief honours with fine examples of *Gleichenia dichotoma*, *G. Mendelli*, *Cibotium regale*, and *Microllepia hirta cristata* among others. Mrs. Cole & Sons followed with a less even collection, but including neat plants of *Davallia Mooreana* and *Cyathea dealbata*. In the class for four Mr. Berry had good examples of *Gleichenia rupestris*, *Adiantum cultratum*, and *Davallia Mooreana*, being placed first, followed by Mr. Nash, gardener to Captain Starkey. R. B. Dodgson, Esq., Blackburn, had the best single specimen, a *Cyathea dealbata* over 6 feet high and very fresh. Mr. T. Simpson followed with *Dicksonia antarctica*, also healthy.

**Hardy Ferns.**—For six hardy Ferns Mr. J. Buckle, York, obtained the first prize with very vigorous *Lastreas*, *Athyriums*, *Scolopendriums*, and *Polystichums*, several good varieties being represented. Mr. Rodwell was second with a similar collection, in which *Asplenium marinum* was remarkable for its size and freshness. Mr. Buckle was also first with a single specimen hardy Fern—*Athyrium cristatum*, very fine; Captain Hinch was second, and Mr. Dodgson third. Only two collections of thirty-six British Ferns were exhibited—namely, by Messrs. Rodwell and Buckle, who were first and second respectively with fine selections of varieties, the plants being in excellent condition. *Selaginellas* were contributed by Messrs. J. Buckle and Berry in fair condition, but rather unsatisfactory as regards nomenclature.

**GROUPS.**—A large tent was devoted to these, and several tasteful arrangements were contributed in the class for a group to occupy a space not exceeding 200 square feet. Mr. Letts was easily first with a light and elegant group, having a central specimen of *Cordyline australis*, a groundwork of *Begonias*, *Coleuses*, *Spiræas*, *Pelargoniums*, and other flowering plants, among which were placed taller slender Palms, *Dracænas*, and Ferns that imparted a very graceful appearance to the group; moreover, it was not too crowded—a fault that marks too many such arrangements. Mr. Berry was second with a much more formal, and consequently less pleasing group, though it contained good healthy plants. Mr. R. Simpson, Selby, and Mr. McIntyre were third and fourth respectively with groups similar in character to the second. In the class for a group arranged for effect in a space of 100 square feet several extremely formal arrangements were contributed, the plants arranged on stages in pyramidal form. Gowthorpe and Mr. Fry were the chief prizetakers, but four or five similar groups were staged, their chief recommendation being their brightness.

**Cut Flowers.**—Several classes were devoted to these, and in the competition was keen, and the flowers staged of good quality. Roses were especially abundant, and though there was a want of substance in several stands, still they were generally satisfactory for the season. Messrs. Jackson & Co., H. May, and Eastwood were the chief prizetakers in the large classes, while in some of the smaller classes Mrs. Grimston, E. R. Whitwell, Esq., and Mr. G. Kirken secured the most important awards. Miscellaneous stove and greenhouse flowers were well shown by Mr. McIndoe, Mr. Cartwright, and R. Ducheson, Esq.; hardy flowers being superbly represented by Messrs. R. Smith & Son, Worcester, who were the only exhibitors in the class, and secured the chief prize. Bouquets, buttonholes, and ornamental vases were staged

by Messrs. Rylance, Wright, and Ducheson, who were awarded the most important prizes in all the classes.

**FRUIT.**—Visitors to York Floral Fête generally expect a good display of fruit; in fact, it is usually the first large Show of the year where fairly representative collections are staged. This is partly due to the time at which the Show is held, being neither too early nor too late for the indoor productions; and as the period selected suits the district, competitors are usually numerous and their exhibits satisfactory. Last week was no exception to the rule, all the principal classes being well filled, and the fruit staged fairly ripened, and in some cases of first-rate quality. The chief class was that for ten distinct varieties of fruits, to include not more than two sorts of Grapes, two of Pines, two of Melons, and two Peaches. Three good collections were contributed, the premier award being secured by Mr. Coleman, gardener to Earl Somers, who had two fine bunches of Black Hamburgh Grapes well ripened and bearing abundant bloom, the same number of bunches of Foster's Seedling of fair size but rather green, a pair of even Pines of moderate size, the varieties being Charlotte Rothschild and Queen; Golden Gem and Eastnor Castle Melons were fine, the former particularly well netted and ripened. Violette Hâtive Nectarines and A Bec Peaches, Sir Joseph Paxton Strawberries and Brown Turkey Figs, completed this collection, which merited the honour accorded for it. The second position was obtained by Mr. McIndoe, gardener to J. W. Pease, Esq., Hutton Hall, Guisborough, who staged very neat and praiseworthy examples of well-selected varieties of fruits, some of the most noticeable being Muscat of Alexandria Grapes, Barrington Peaches, May Duke Cherries, and Best of All Melons. Mr. Mann, The Gardens, St. Vincents, Grantham, was a good third; his fruits, Sir Garnet Wolseley Melon, being very fine and remarkably well netted. For six varieties Mr. Wallis, gardener to Sir H. M. Thompson, Bart., Kirby Hall, York, carried off the chief prize for ripe and handsome Black Hamburgh and Buckland Sweetwater Grapes, and good Peaches amongst others. Mr. W. Coleman followed closely, his Black Grapes also being fine, and Mr. McIndoe was placed third with fruits but few points behind the foregoing; indeed all the collections in this class were close in merit. An extra prize was adjudged to A. Wilson, Esq., for well-ripened Grapes, Peaches, and Strawberries. Collections of four varieties was shown by Mr. R. Westcott, gardener to the Duke of Cleveland, Raby Castle, and Mr. McIndoe, who secured the first and second prizes in that order.

**Grapes.**—These were generally of satisfactory quality. The best black Grapes were from Mr. Coleman, consisting of the variety Black Hamburgh, large in bunch and berry, and superbly finished. Mr. J. Allsopp, gardener to Lord Hotham, was second with the same variety but smaller bunches; Mr. Jones, gardener to R. Warrell, Esq., being third with large bunches, but deficient in bloom. The competitors were numerous in this class, seven entering the lists. Five dishes of white Grapes were contributed. Mr. G. Cartwright was first with Buckland Sweetwater, finely ripened bunches of moderate size; Mr. Allsopp second with fairly good Foster's Seedling; and Mr. T. Beckett, gardener to Alderman Terry, third with the same variety not quite so ripe. The first prize for a bunch of new Grapes was awarded to Mr. McIndoe for a fine example of Duke of Buccleuch.

**Peaches and Nectarines.**—Mr. McIndoe secured the chief award for a single dish of Peaches with even, well ripened, highly coloured, but moderate-sized fruits of Barrington; Mr. Hutton, gardener to Thomlinson Walker, Esq., York, and Mr. Wallis following closely with good fruits. Mr. Coleman staged the best Nectarines, Violette Hâtive, of excellent quality; and Mr. McIntyre was second with rather small but finely ripened Welbeck Seedling. In the preceding class there were five entries, but in the last-named only two.

**Melons.**—Ten green-fleshed Melons were in competition, the best being an example of Colston Basset, of good size and well netted, from Mr. Coleman; Mr. T. Osman, gardener to R. B. Dodgson, Esq., following with a similarly good William Tillery; and Mr. Clayton, gardener to J. Fielden, Esq., was third with Eastnor Castle in good condition. Six scarlet-fleshed Melons were staged, all of creditable quality. Messrs. Cartwright, Mann, and Allsopp being awarded the prizes in the order named.

Figs and Cherries were shown in fair condition by Messrs. Coleman, McIndoe, Wallis, and Mann, but Strawberries were rather poorly represented.

Vegetables were not very abundant, and as a rule there is no provision for them; but this year Messrs. Backhouse & Son offered three prizes, value £3 and £2, and a third value £1 was given by the Society for ten distinct stands, and six collections were staged of very good quality; Peas, Beans, Potatoes, Mushrooms, and Tomatoes being especially fine. Mr. Kirk, Mr. Cartwright, and Mr. J. Hammond, gardener to A. J. Cholmley, Esq., were the prizetakers. Twelve braces of Cucumbers were exhibited, all of moderate size, even and bearing good bloom. Messrs. J. Williams, C. Rylance, and Mann were awarded the prizes.

Among the exhibits not for competition were some handsome collections from Messrs. Richard Smith & Son of Worcester, including Spanish and German Irises, Pæonies, Pyrethrums, and Clematises, representing many beautiful varieties. An extra prize was awarded for these, and a first-class certificate for Clematis Princess Beatrice, a fine variety with very large flowers of excellent form, and a delicate pale mauve or lavender colour. Mr. W. H. Hilton, Liverpool, was also accorded a prize for a collection of ornamental flowerpot covers,

Several other groups and miscellaneous contributions were staged, but none of the metropolitan firms were represented—a rather unusual circumstance.

### HARDY BROCCOLIS FOR SUCCESSION.

As last winter was what may be termed a test season for Broccoli, I submit my experience on the subject. I found that Model has proved itself almost the only Broccoli that stood the winter, owing in a great measure to its short sturdy growth; its value is also enhanced by its lateness, figuratively speaking shaking hands with the early handlight Cauliflowers. Cattell's Eclipse is a good late variety. Two years ago I cut heads firm and compact on the 28th of June, but I do not find it so hardy as Model. Suttons' Queen was next in hardiness to Model, but other varieties were nearly all killed. By growing about seven varieties (and I should advise the following:—Veitch's Autumn Protecting, Knight's Protecting, Leamington, Wileove, Suttons' Queen, Cattell's Eclipse, and last but not least, Model)—everything, I think, is attained in the way of Broccoli that can be desired.—J. GADD.

### SOUTH ESSEX FLORICULTURAL SOCIETY.

JUNE 15TH.

A QUARTER of a century has now elapsed since the establishment of this Society, and it still continues to make vigorous progress, annually producing an exhibition which is highly appreciated in the surrounding district, the attendance of visitors being in consequence very satisfactory whenever the weather is in any degree favourable. The ready support thus afforded keeps the Society in good condition financially, and it is pleasing to note that the report for the past year announces a balance of £35. The recent Show fully maintained the credit of the Society, even though there was a slight deficiency in some departments; the general quality of plants and flowers was such as is surpassed at very few local exhibitions, and the arrangement as usual gave much satisfaction. The beautiful grounds of the President, J. G. Barclay, Esq., were in excellent condition, and the privilege of promenading in them, so generously extended to all visitors, appeared to be thoroughly enjoyed. This is undoubtedly one of the great attractions, and judging by the numerous visitors who passed the gates in the afternoon the Show of last week must have been as successful as any previously held.

Two large marquees were devoted to the exhibits, one containing the plants and the other the cut flowers, floral decorations, fruit, and vegetables. In the former the most noticeable features consisted of the stove and greenhouse plants, Orchids, fine-foliage plants, and Ferns, in the classes devoted to which many handsome specimens were staged. Among the first-named the chief collections were in the class for eight specimens, three fine groups being contributed. Mr. D. Donald, gardener to J. G. Barclay, Esq., was placed first with well-grown plants of *Aphelaxis purpurea*, *Genetyllis fuchsoides*, *Dracophyllum gracile*, and a remarkably handsome *Statice profusa*, 5 feet in diameter, flowering profusely, the blooms being of a rich purplish blue tint. Several other smaller plants were also included, constituting a very satisfactory collection. Mr. Bones, gardener to D. McIntosh, Esq., Havering, was a close second with healthy and even specimens; Mr. J. Douglas, gardener to J. Whitbourn, Esq., Loxford Hall, Ilford, securing the remaining award with plants almost equal to the preceding in merit.

Orchids were well shown, and though the majority of the plants were small they were in excellent health, and several choice species and varieties were represented. The principal class was for eight specimens, and in that Mr. Douglas easily secured the first prize with an interesting collection, including a fine *Odontoglossum hastilabium*, with three panicles of flowers; *Dendrobium thyrsiflorum*, bearing five large spikes; *Odontoglossum crispum*, a good variety with two spikes; *Calanthe veratrifolia*; *Masdevallia Harryana*, also in good condition; and several others. The same exhibitor was also first with a single specimen Orchid, exhibiting a beautiful example of *Lælia purpurata* with four spikes bearing fourteen flowers, the lip of an unusually rich purple tint, and indicating a superb variety. Another plant from Loxford Hall also deserves notice—namely, a specimen of *Vanda teres* in flower. This plant is not often seen at exhibitions, indeed many growers experience considerable difficulty in inducing it to flower. On the specimen in question the blooms were large and richly coloured, and the Judges very highly commended the plant. The second collection of eight was from Mr. B. Ship, gardener to J. R. Scott, Esq., Walthamstow, and included, several noteworthy plants, *Brassia verrucosa* and *Cypripedium Stonei* being particularly fine. The second prize for a single specimen was accorded to Mr. T. Foster for a good example of *Dendrobium Devonianum*; and other exhibitors in the class for four plants were Mr. Monk, gardener to W. Fowler, Esq., Leytonstone, and Mr. Merrett, gardener to R. B. Ashby, Esq., Walthamstow.

Fine-foliage plants produced a good display, the majority being healthy clean specimens. The best six in 15-inch pots were staged by Mr. Donald, and included *Cocos Weddelliana*, *Croton Weismanni*, and *Theophrasta imperialis* in fine condition. Mr. Douglas followed closely. These two exhibitors held similar relative positions

with single specimens, the first being a handsome *Croton undulatus*, remarkably well coloured, and the second a good *Cycas revoluta*. Mr. Bones was accorded the premier position for four plants, a well-grown *Croton variegatus* being especially notable. Palms were contributed by Mr. Donald, Mr. Douglas, and Mr. Peters, gardener to W. Pearce, Esq., Wanstead, who secured the prizes in that order for vigorous plants. Ferns were also represented by satisfactory collections, the principal exhibitors being Mr. Jones, gardener to Sir Thomas White, Chigwell, and Messrs. Donald, Douglas, Bones, and Merrett.

Among the smaller classes *Coleuses* were effective, three good collections being contributed by Mr. Monk; Mr. Fisher, gardener to J. Harrold, Esq., Wanstead; and Mr. Peters, who obtained the prizes for generally compact and well-grown plants, especially those in the premier group, in which the varieties Mr. Simpson, Firefly, and Royalty were well represented. *Caladiums* from Mr. Douglas and Mr. Windebank, gardener to Captain Davis, Wanstead, were also attractive; while the *Calecolarias* from Messrs. Bones and Foster

were very bright, compact, and well flowered; Messrs. Monk, Merrett, and Fisher staging smaller examples. Some neat and dwarf *Hydrangeas* were exhibited by Mr. Biggs, gardener to G. Borwiek, Esq., who also contributed the best *Gloxinias*. A collection of unusually dwarf *Cockseombs* from Mr. Windebank attracted much attention, as the heads were also large and well coloured. *Pelargoniums* showed the effects of the season, and were by no means up to their usual condition. Several other collections were also staged by the exhibitors already named, but the only one in the plant tent that calls for special notice was a fine group of new and choice plants from Mr. B. S. Williams of Upper Holloway, which was greatly admired by the visitors.

Cut flowers were shown in large numbers and in excellent condition, some of the general collections being the finest we have seen this year. Messrs. Douglas, Foster, Monk, and Merrett were the chief prizetakers for stove, greenhouse, and hardy flowers; while for *Roses* Mr. Day, gardener to E. Tewson, Esq., Walthamstow, Mr. Mallett, and Mr. Learing, gardener to J. Pelly, Esq., Chigwell,

Fig. 112.—CROTON LADY ZETLAND.

secured the principal awards. For vases Mr., Mrs., and Miss Abbott were the most successful exhibitors, having some very tasteful arrangements. Fruit was not abundant, but Mr. Donald had some well-finished bunches of Black Hamburg Grapes; Cherries, Strawberries, and Apples being exhibited by Messrs. Douglas, Donald, Learing, Windebank, and Day. Several good collections of vegetables were staged by Messrs. Donald, Fisher, and Bones.

The above is a brief outline of the chief features of the Exhibition and a record of the principal prizetakers, the great demand upon our space not permitting a more lengthened reference to details. A word of credit is, however, due to the Secretary, Mr. C. E. Cox, for the admirable arrangements both in the disposition of the plants and the notification of the awards.

#### CROTON LADY ZETLAND

CROTONS are now very numerous, yet new and elegant forms are being sent out yearly, usually possessing some distinctive

characters that attract attention and ensure their acceptance by the horticultural world. Mr. B. S. Williams of Upper Holloway, has already sent out many beautiful varieties, several of which have deservedly acquired a standard position in gardens, and the one represented in fig. 112 is one of the novelties for the present year from the firm above named. As will be seen by the engraving, the variety is one of the narrow-leaved forms which, though less noble or imposing than those with broad leaves, are much more elegant, and in a young state are admirably suited for table decoration. *Croton Lady Zetland* is something in the way of *C. Macfarlanei*, but is greatly superior to that variety, the colour being brighter and earlier developed—two recommendations of much importance. The leaves are an inch or a little more in breadth, and 8 to 12 inches long, gracefully arching. The midrib is bright crimson varying to orange, the blade of the leaf being irregularly marked with dark green and bright yellow. A plant was exhibited by Mr. B. S. Williams at

Regent's Park in April of the present year, when a certificate was awarded for it; and though the specimen was only of moderate size, the richness of the colours indicated the value of the plant in a young state. The introducers have favoured us with the accompanying woodcut, which will convey a very fair idea of the variety.

### THE POTATO CROP.

I GREW altogether, in different parts of the country, thirteen acres of Potatoes last year, and intended to send a detailed report to the Journal, but was too unwell to do so. It will perhaps suffice to say that the experiment was very successful as far as regards growing good crops, with but very little disease; but Potatoes have been so plentiful that the price has ruled low.

Good samples of Magnum Bonum have been sold lately at 1s. a peck retail, and the smaller tubers at 8d., while large quantities of Early Rose have been sold during the season at 8d. a peck. I do not think we have had much occasion to trouble the foreigner this year for Potatoes; certainly not anything like to the extent of former years, and, as I say in my book, I do not think we need do so now we have the Magnum Bonum and Scotch Champion to depend upon. These Potatoes will save us millions of money. It is to be hoped we shall soon have some more of the same character. I have one seedling, a second early, which is promising. The price of the Magnum Bonum this year has certainly been rather too low to be pleasant for the grower, but I think we should endeavour to meet the lowness of price by following less expensive modes of cultivation than are generally adopted. I am rather inclined to modify my remarks with regard to the distance between the rows. Three feet may be all very well in rich soil or where it has been highly manured, but where Potatoes are grown in fields of ordinary farm land, which is not generally very rich, I should prefer 2 feet 6 inches or 2 feet 8 inches for the Magnum Bonum.

The crops here are looking very well at present, and promise a good yield, having escaped the frost of the early part of this month.—THE AUTHOR OF THE BOOK ON POTATO DISEASE.

### THE COMMISSIONERS FOR THE EXHIBITION OF 1851 v. THE ROYAL HORTICULTURAL SOCIETY AND PERCIVAL DE CASTRO, A DEBENTURE HOLDER.

THE following is the full text of the judgment of Mr. Justice Fry, as delivered in the Chancery Division of the High Court of Justice on the 15th inst.

MR. JUSTICE FRY:—This is an action brought by the Commissioners of the Exhibition of 1851 against the Horticultural Society and the representative of certain debentures issued by the Society, in which the plaintiffs seek to gain possession of the Horticultural Gardens at Kensington.

The agreement of the 24th of July is that which constitutes the principal bond between the respective parties to this action. It is quite true that there are subsequent agreements, by one of which an increase was made in the sum payable for rent or in the name of rent, and by some of the subsequent agreements certain conditions were imposed on the right of re-entry. I refer to them now only to observe that Mr. North, on behalf of the plaintiffs, has contended that those subsequent agreements create no difficulty in the way of the relief which he asks, and the learned counsel for the defendants have not insisted that they do create such a difficulty; and, therefore, my whole attention in the subsequent part of my judgment will be directed to the agreement of the 24th of July, 1860.

The circumstances under which that agreement was entered into were shortly these:—The Commissioners were constituted for the purpose of promoting certain objects connected with art and science. They were the owners of considerable property in the neighbourhood of the intended gardens, and they were the owners of the site of the gardens itself. The Horticultural Society had received contributions to the extent of £10,000 to be laid out upon the gardens, and the substance of the agreement between the parties was this, That the Commissioners should make over to the Horticultural Society the land in question for a term of thirty-one years; that the Commissioners should expend on improvements in land and levelling, and the erection of arcades, a sum of £50,000; and that the Horticultural Society should expend on the land £10,000 which they had already received by way of contributions, and a further sum of £40,000, which they intended to raise by way of debentures; and that the receipts arising from the gardens should be applied in a certain specified manner between the parties to the contract. Now that manner was shortly this: It was provided that out of the receipts from the gardens there should be retained by the Society "such a sum as shall from time to time be allowed by the Committee hereinafter mentioned" in respect, first, of the expenses of the Chiswick gardens, secondly the expenses of the Society generally, and thirdly the current expenses of the Kensington gardens. Then the instru-

ment declared that the allowance should from time to time proceed, and be made upon a fair and reasonable basis, and so as to keep and maintain the gardens and all the buildings, improvements, and ornaments upon and belonging thereto in thoroughly good order and condition. Then, secondly, the agreement provided that "there shall be then retained by the Society out of such receipts" the interest at the rate of five per cent. upon the debentures—£40,000—or such other sum as should be subsisting. Then, thirdly, it provided "there shall then be paid by the Society to the said Commissioners as rent the yearly sum of £2145, if the receipts shall be adequate for such payment after retaining to the Society the sums authorised to be retained by them under the first and second heads of the present clause; but otherwise such a sum only as shall be equal from year to year as the residue of the receipts over and above the sums so in precedence." Then the instrument provided that "if there shall remain any surplus over and above the said several payments herein-before directed to be made or retained out of the 'receipts from the gardens,' there shall be paid to the Commissioners for their own use and as additional rent yearly a sum equal to half such surplus." A moiety of the surplus, therefore, was retained by the Horticultural Society, and it was provided that they should devote and apply towards the liquidation of the £40,000 debenture debt three-fifths of the money actually received by them from time to time in respect of the receipts from the gardens after payment of the three sums directed to be paid under Clause 14 of the agreement.

Then comes in Clause 18 the provision with regard to re-entry, upon which the plaintiffs are now insisting. "In case it shall happen after the expiration of the first five years of the lease that the sum or sums payable thereunder to the Commissioners as rent shall fail in every one of any five consecutive years subsequent to the first five years to be equal to the sum of £2145 per annum, then and in any such case it shall be lawful for the Commissioners to re-enter upon the said demised premises, and to resume full and absolute possession thereof with all improvements therein and all erections thereon, and with all the plants, shrubs, and trees in and about the same, and out of whatever fund the same may have been paid for, and that without making any compensation whatever to the Society." Then there was a proviso that the right of re-entry should not arise if the Commissioners from the commencement of the term had received upon the average £2145.

The plaintiffs allege that in the five years beginning from the 1st June, 1873, and ending on the 31st May, 1878, the sum payable to them as a rent had failed to reach the sum of £2145. That sum was increased to £2400; but that is immaterial for the present purpose, and they have shown to my satisfaction that nothing in fact has been paid in those five years in respect of rent.

That being the nature of the claim of the plaintiffs, the defendants have resorted to a great variety of arguments to resist the plaintiffs' claim. There are many of those which I think I need only refer to by saying that they do not weigh in my mind at all. It has been said that there has been a defect of pleading, because the statement of claim has not stated the exact date at which the alleged forfeiture arose; and certain old cases were referred to with regard to pleadings in ejectment before pleadings in ejectment were abolished, as they were by the Common Law Procedure Act years and years ago. Those cases appear to me to be immaterial. The pleading in this case if not adequate was sufficient at any rate when it came on for hearing, because the defendants if they were embarrassed might have applied to have the pleadings amended.

Then it has been said that a demand for rent was necessary, and no demand was made. But it is apparent, from what I have read, that the right of re-entry in question is not a right of re-entry for non-payment of rent, but because a certain sum arising from a particular fund does not equal a given named sum. It is a default of equation, not re-entry for non-payment of rent; and the idea that the rent that did not exist should be demanded appears to me somewhat difficult to understand.

It has been further argued, on behalf of the debenture holders, that a partnership has been constituted between the Commissioners and the Horticultural Society, and that for some reason or other, which I am afraid I fail to apprehend, that partnership would prevent one of the partners from enforcing his right of re-entry if it existed. In my view, if one partner lends to a partner whose rights are defined by an instrument, and lends to that partner on the faith of that instrument, the instrument must have effect given to it, although a partnership may be constituted by it. A lender who lends on the faith of a term determinable under the instrument of partnership cannot say that that term is not determinable.

There remains, however, in my judgment a very important question for consideration, and that arises from the facts with regard to the Committee. I have already pointed out that the instrument of 1860 proposes the appointment of a Committee. That Committee was to be appointed for the purpose of regulating the amount to be retained by the Society. In each year it was to consist of three members appointed by the Commissioners and three by the Horticultural Society, and was to be presided over by one of the members appointed by the Commissioners. I have pointed out that the instrument of 1860 contemplated the raising of debentures upon the faith of it, and the debentures were raised on the faith of that instrument, and the sums that were provided for the payment of interest and the payment of principal by that instrument were by the

debentures pledged to the debenture holders. They therefore acquired a most material interest in the sums which were to arise from the gardens, and they acquired, therefore, a material interest in seeing that the term created in those gardens and demised to the Horticultural Society is not put an end to except in accordance with the terms of the instrument on the faith of which they advanced their money; and considering that the instrument was framed between the parties with a view to raising the money, I think the debenture holders are entitled to say that they stand in a position somewhat different to that of persons who claim merely under one of the two contracting parties.

Now, the Committee did not meet in the year 1873. There was a *bonâ-fide* difference of opinion between the Society and the Commissioners with regard to the propriety or impropriety of the appointment of the three members named by the Horticultural Society. The Committee did not meet in 1874, and for the same reason. In 1875 that difficulty was removed, but the Committee did not meet then, although it was undoubtedly, as it appears to me, in the power of the Commissioners to have required the Committee to meet then. In 1876, 1877, and 1878 the same thing happened, and the Committee in fact never met from some time prior to 1873 down to the present hour. In point of terms it appears to me to be plain that the allowance by the Committee is necessary for the ascertainment of the expenses, and in point of substance I think the meeting of the Committee was a matter of great importance. The evidence before me tends to show (I do not say it conclusively shows) that in some of the years if the Committee had met and exercised the vigilance with regard to expenses which they had exercised in previous years the portion of the money payable by way of rent might have been paid to the Commissioners; and if the interference of the Committee was essential or important to the settling of the expenses, it, of course, affected all the subsequent sums, because until the expenses had been paid the debenture holders could not be paid, and until the expenses and debenture holders had been paid the sums payable by the Society by way of rent could neither be paid nor ascertained, and therefore the question whether the sum or sums payable under the agreement to the Commissioners for rent did fail in the five years appears to me to turn on whether the prior charge by way of expenses had or had not been ascertained, because until the ascertainment of the prior charge you cannot tell whether the subsequent sum exists or no. I think, therefore, that in point of substance as well as in point of form the sum payable has never been ascertained, and it is impossible therefore to say that that sum has failed.

Then, no doubt, it has been argued with great force that the Horticultural Society have estopped themselves from setting up this contention because the accounts of the Society have been produced before me, and although those five years are not measured from the same dates, yet during the whole period covered by the five years to which I have referred the whole expenses of the Society were, together with the debenture interest in certain years, sufficient to consume the whole receipts from the gardens, and left nothing whatever payable by way of rent to the Commissioners. I have a difficulty in saying that those accounts worked the estoppel contended for. In the first place they may prevent the Society from saying that the expenditure was not perfectly *bonâ-fide* on their part; but it does not follow that their judgment of what was right to be expended and the judgment of the Committee as to what was right to be expended would necessarily agree. They are two bodies who might have differed honestly one from the other, and I am unable to come to the conclusion that there is any estoppel in those accounts on the Society which would prevent them from saying that the Committee might have allowed smaller sums.

Then in the next place there is this difficulty, that for such an estoppel to be fair, and to be that which can be relied upon, it must be mutual. The Commissioners must be prevented from saying that the accounts can be opened, as well the Horticultural Society must be prevented from saying that they did not fairly expend all the money. I am at a loss to see how the Commissioners are prevented from saying that a portion of that money was improperly expended in the expenses of the gardens. If the consent of the Committee was a condition precedent to the outlay by the Horticultural Society, then, as that consent was not given, not a farthing of those sums can be allowed to the Society; if it was not a condition precedent, then the accounts are open between the parties, and the Commissioners might still be heard to say that a portion of the sums so expended on the Horticultural Society's expenses was improperly expended by them. Again, I am at a loss to find any precedent for holding that a term can be extinguished by estoppel. According to my view a forfeiture, if it is to take effect, must take effect according to the very terms of the instrument, and I have great difficulty in saying that the allegation by the Horticultural Society that they fairly expended those sums in the absence of the Committee to guide them, precludes them from saying that the sum payable by them to the Commissioners by way of rent has never been in fact ascertained in the manner expressed.

It has also been argued that by the effect of the instrument of 1876 the Horticultural Society have again estopped themselves from setting up this contention. I do not so read the recitals in the instrument. They refer to the past receipts during certain years as having been insufficient for the payment of all the sums charged by the fourteenth clause of the agreement of 1860. They recite in anti-

cipation that in the year 1876 the Commissioners may become entitled to exercise the right of re-entry for non-payment of rent. Under what circumstances that anticipation arose I do not distinctly know, but it does not appear to me to be a conclusive admission between the parties that the deed is to operate in any other manner than that which, according to its terms, I hold it ought to operate in.

But even supposing there was an estoppel as against the Horticultural Society, which would prevent their saying that the rent payable had been ascertained, and that no such sum existed because no payment was made, it remains to be inquired whether the debenture holders are in any manner bound by the estoppel. I have already indicated my opinion that the contract of 1860 was made for the purpose of enabling the Horticultural Society to raise money upon it, and I think the debenture holders are entitled to every security and every safeguard which that instrument intended to provide for them. One of those safeguards was the appointment of this Committee. In the appointment of that Committee the debenture holders and the Commissioners had similar interests. They were both interested in cutting down the expenses to a reasonable extent, because each of them had a charge upon the proceeds of the gardens subsequent to the expenses. They must be taken, therefore, to have advanced their money upon the faith of there being a Committee appointed in the manner indicated by the deed, which should act from time to time in their interest, which should ascertain the expenses, and, therefore, ascertain the sum payable by way of rent ascertainable as between the parties; and they must be taken further, in my view, to have contracted that the term of thirty-one years shall be put an end to only in the event of the sums payable by way of rent being ascertained and being found for five consecutive years not to equal £2145.

In my judgment, as I have already indicated, the sum payable by way of rent has never been ascertained, because the prior expenses have never been ascertained. The debenture holders, therefore, I think, are in a position to say, "You have contracted between yourselves for the creation of a term determinable on a certain event only; you have induced me to lend money on the faith of that term, or upon the faith of raising a charge upon the money arising from the term; you have, therefore, given me an interest in the continuance of the term. It has been stipulated that that term shall only be extinguished in the event of a certain sum failing to meet another, which event has never happened, because you have, by disagreement between yourselves, never provided the machinery for ascertaining the amount of the prior sum."

I hold, therefore, that the forfeiture upon which the plaintiffs rely has not arisen; consequently that their claim made in the present action is not sustainable, and I dismiss the action with costs.

#### CRICKETS IN CUCUMBER HOUSES.

To "A CORNISH SUBSCRIBER," who is troubled with crickets in his houses, I would say that he cannot do better than try phosphor paste in the following way—Cut some thin slices of bread and butter, and upon this spread a moderately thick layer of the paste. Cut the bread into pieces of about an inch square, and lay them about in the haunts of the crickets. If they do not partake the first night or two they do so eventually, and in a few days many of them will be found dead, and if the practice be continued they will be all destroyed.

I have been much troubled with them this spring eating the young roots of Orchids, and getting among and eating the tips of the roots of Pines, besides making great destruction in the Peach house, as well as eating ravenously the Cucumbers and Melons, also nearly all cuttings and seedlings in the propagating house have been eaten by them. I at first tried various insect-destroying powders, but none answered so effectually as phosphor paste. After one night in these heated structures the paste becomes dry and the bread hard, so that it must be renewed and a fresh supply provided. I purchase the paste in small penny bottles, because when a bottle is once opened the paste loses strength. It will destroy anything that will eat it, and should be laid down the last thing at night and removed early in the morning.

I have also been much troubled with mice in one of the newly made Vine borders, and they have been destroyed by the same means. A house was planted last year with seventeen Vines, and the mice ate through the stems of eleven of them during last winter. Has any one known of such a case as this before?—THOMAS RECORD.

I NOTICE in last week's Journal that a correspondent from Cornwall is troubled with a plague of crickets. A few years ago, when living in Manchester, we were infested with crickets and cockroaches. We procured a box of Hardeman's beetle powder, which drove both these pests away in a very short time.—JAMES PERCIVAL.

BEDDING PELARGONIUMS.—"C. P. P." deserves honour for continuing to cultivate Pelargoniums through all the years the

runners to and fro after new things have been neglecting them. I believe in a few years we shall see more Pelargoniums grown than ever. I have tried many of the newer varieties, but have returned to the old kinds. Vesuvius is at present the only really fine scarlet bedding variety with me, but even it would be improved with a greener leaf. The large-trussing sorts always become dirty-looking here. I imagine it would repay anyone with the means to breed a strain of bedders after Vesuvius. Were not A. F. Barron and The Shah raised by Mr. George of Putney Heath? I do not think the leaves of Sophia Dumaresque will do more than form roots. In raising stock of new varieties quickly I have occasionally struck leaves with eyes attached, and have found where the eye was absent at the base of the petiole that, although roots were formed, no growth was in any one instance ever made.—R. P. B.

### ROSE SHOW FIXTURES.

THERE has been but little alteration in the fixtures of our numerous Rose shows, and everything promises well for a successful season. It will be a matter of satisfaction that the lessees of the Alexandra Palace, yielding to the remonstrance of the Committee of the National Rose Society, have restricted its exhibition to one day—a gracious act on their part, which will, I hope, lead to their having a very excellent show, and to the hearty support of those members of the Society who are exhibitors.

July 22nd .. .. .	Sutton Coldfield.

I am not quite sure as to Oxford or Newton Stewart, but think the list is correct.—D., Deal.

WE may remind our readers that on Tuesday and Wednesday next, the 28th and 29th inst., the ROSE SHOW OF THE ROYAL HORTICULTURAL SOCIETY will be held in conjunction with the PELARGONIUM SOCIETY'S SHOW, the Evening Fête also taking place on Tuesday. A number of special prizes will be offered, in addition to the liberal provision in the schedule, by the General Horticultural Company for groups of plants, Messrs. Laing & Co. for Begonias, Messrs. Webb & Co. and Rivers & Son for fruit, Messrs. Sutton & Sons, Carter & Co., and Webb & Sons for vegetables.

— THE finances of the NATIONAL POTATO EXHIBITION appear to be in a satisfactory state, the balance in hand being more than twice the amount of that recorded in the audit account of the preceding year, and now exceeds £50.

— MR. ANTHONY WATERER'S RHODODENDRONS in the Royal Botanic Gardens, Regent's Park, are now in fine condition, and the display is, perhaps, the best that has been seen in the gardens. The shrubs are pleasingly arranged, the various colours being so associated as to show the varieties to the best advantage. Some of the specimens are extremely fine, and all densely flowered. Nearly all the best varieties in cultivation are represented, and the exhibition is in all respects highly satisfactory.

— MANY of our readers will be glad to learn that the ALEXANDRA PALACE ROSE SHOW on July 9th will continue for one day only, not extending over two days as was originally proposed. The fixtures of some other of the Shows on Muswell Hill have been changed. The Rose Fair and Gooseberry Show will be held on July 16th, and the Lily Show and table decorations on August 6th. As stated last week the Strawberry and Cherry Exhibition will be held on July 1st and 2nd.

— THE "Prairie Farmer" publishes the following relative to GIRDLED TREES—"A Wisconsin correspondent writes that field mice or rabbits have girdled several choice Apple trees on his place, and wants to know how to save them. This can be done by bridging over the girdled space with twigs of the same wood connecting the bark above with that below. A sharp narrow chisel is driven into the bark, and twigs cut the right length and sharpened at each end are inserted in the incisions thus made. The wounds should then be covered with grafting wax."

— FOR covering the back walls of plant stoves and providing a face of dark green foliage as close almost as if glued to the wall, perhaps no plant can equal *FICUS REPENS MINIMA*. A wall thus covered in the gardens of N. Clayton, Esq., East Cliffe House, Lincoln, is admired by all who see it. The house in which the Ficus is growing is kept at a high temperature for Crotons, Anthuriums, Nepenthes, &c., which are admirably grown. But fine as the plants are, the back wall, instead of being as unsightly as such walls often are, is the finest feature of the house. The wall is lofty, and the Ficus after reaching the top and having nothing else to cling to hangs over the path gracefully, and by contrast enhances the appearance of the smooth portion of the wall. This Ficus will grow in greenhouses, and has even passed the winter in the open air; but it evidently delights in heat and moisture, and in the house in question produces an effect as attractive as it is undoubtedly unique.

— IN one of the vineries of the same range of glass the DUKE OF BUCCLEUCH GRAPE is growing and fruiting as freely as the Black Hamburgh. The Vine is on its own roots, and is bearing seventeen bunches, principally on what may be termed very long spurs, Mr. Wipf finding that close pruning is not conducive to fruitfulness; and he appears to work on the principle of pruning to the best bud, whether that is 2 or 6 inches from the main rod. Another Vine is growing well on the Muscat stock to which it has been attached; it is bearing one bunch, and the influence, if any, of the stock on the fruit is being waited for with some interest. The fruit of the Duke is much esteemed at East Cliffe House.

— IT is not often that a hedge of the GOLDEN ELDER (*SAMBUCUS NIGRA AUREA*) is seen in gardens, but when grown in that form and well coloured it is remarkably attractive. We recently observed a very fine example of this, a villa garden of moderate size having a dense brightly coloured hedge on three sides, 4 or 5 feet in height. The yellow tint was much better developed than is sometimes the case, and in consequence there was an absence of the sickly hue that occasionally characterises the shrub near towns.

— IN continuation of the second series of LETTS'S POPULAR ATLAS we have received parts 14, 15, and 16, containing five maps each, representing in sections on an enlarged scale England and Wales, Ireland, Canada, and India. Excellent watershed maps of England are included, also one showing the geological characters of the environs of Edinburgh. The execution of the work continues as satisfactory as in the first series.

— WE have received the small but neat catalogue of the DISS HORTICULTURAL SOCIETY'S SHOW, which is to be held on July 12th, in which Roses have the post of honour, special prizes of substantial value being provided. In the open class of twenty-

four single blooms there are four prizes, the first being £5; and for twelve Teas and Noisettes, open to nurserymen and amateurs, the first prize is £2. The Rev. F. Page Roberts of Scolt Rectory is the Secretary of the Society.

— A CORRESPONDENT writes to us as follows on VEGETATION IN THE NORTH-WEST RIDING OF YORKSHIRE:—"The country looks at its best now, and never in my recollection were the Thorns, Lilacs, Laburnums, &c., so beautiful. Forest trees are full of flower. Pears and Plums will not be a heavy crop—the latter not half so many as last year. Laurels and Aucubas have suffered terribly the last two winters, but we have not lost one dwarf Hybrid Perpetual Rose through frost. The end shoot of tens of thousands of forest trees have had to be pruned, but are now making fine growth. I was at the Duke of Devonshire's seat (Holker Hall) last week; the Araucarias and some other Conifers thrive well in that locality, and indeed all through the Lake district."

— THE Newport Pottery Company (Rogers & Co.) have sent us samples of their GLAZED FLOWER POTS. The exterior is bright brown, smooth, and impervious to water. One pot is not glazed quite to the bottom, but with what object we are at a loss to conceive. A rustic pot resembling the stump of a tree is very ornamental. It stands on a raised rim in a saucer to match, but we think if there were three apertures in the said rim to aid the passing away of superfluous water it would be an advantage. That glazed pots are suitable for plants has been proved by Mr. David Thomson of Drumlanrig, and Mr. Woodhead, a noted Auricula grower in Yorkshire. Plants in these pots require less water than those in the ordinary pots in general use. The former, however, are necessarily somewhat more costly than the latter.

— FORGET-ME-NOTS are always admired, especially the useful *Myosotis dissitiflora*; but there is another species less frequently grown, and not equalling the one named in effectiveness, yet it is so distinct in the colour of the flowers that it well repays for attention. This is *MYOSOTIS AZORICA*, of dwarf habit, with narrow oblong leaves, and short spikes of purple-violet flowers, which are freely produced. It is especially suited for culture in pots, and when arranged with the other light blue-flowered forms it presents a striking contrast.

— THE CANTERBURY ROSE SHOW will be held under distinguished patronage on the 30th inst. An open nurserymen's class is provided for thirty-six varieties, the first prize being £6. A class for twelve Teas and Noisettes open to all, the first prize £3; one open to amateurs, the leading prize £5; and another for twelve blooms of any varieties. In the local classes the National Rose Society's silver medal will be awarded for the best box of Roses irrespective of numbers, and the bronze medal for the best Rose in the same classes; also a silver cup, value five guineas, is given by C. Stuart Hardy, Esq., of Chilham Castle, for twelve blooms, six Hybrid Perpetuals and six Teas or Noisettes. "Cheshunt Hybrid and all other Hybrid Teas are excluded from the Tea and Noisette classes."

— THE closing monthly meeting of the METEOROLOGICAL SOCIETY for the present session was held on the 15th inst. at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. Eleven gentlemen were elected Fellows of the Society—viz., F. Crowley, A. M. Davis, Rev. R. Drake, F. H. D. Eyre, W. M. Gibson, E. W. Mathew, J. P., D.L., J. Parnell, M.A., F.R.A.S., J. Rigby, T. G. Rylands, F.L.S., F.G.S., H. Smith, and A. H. Wood. The following papers were read:—1, "The Use of Synchronous Meteorological Charts for Determining Mean Values over the Ocean," by Charles Harding, F.M.S. 2, "The Climate of Fiji," by R. L. Holmes, F.M.S. This paper gives the results of meteorological observations taken at Delanasau, Bua, Vanua Levu,

during the ten years, 1871–80. 3, "Note on the Formation of Hail," by J. A. B. Oliver. 4, "Note on a Comparison of Maximum and Minimum Temperature and Rainfall Observed on Table Mountain and at the Royal Observatory, Cape Town, during January and February, 1881," by John G. Gamble, M.A., M.Inst.C.E., F.M.S. Mr. E. J. Spitta exhibited and described a new mercurial maximum and minimum registering thermometer.

— "VICK'S American Monthly Magazine" has the following upon *CAMASSIA ESCULENTA*:—"Camassia esculenta, the Quamash or Quamass of the Indians, is a member of the Lily family, and grows in all the western section of the country, from British America to California and Utah. The root is eaten by the Indians, as it abounds in starch, and is often an important source of their food supply. The pale bluish-violet flowers are borne in spikes raised about 18 inches high. This plant has been in cultivation for half a century, and is much prized by those acquainted with it. Some varieties of it have been produced from seed, and one, *C. Browni*, is considered quite an improvement on the parent species on account of larger spikes of bloom. East of the Mississippi, over a great breadth of territory, is found another species, somewhat smaller in size in all its parts, and with flowers of a lighter shade; this is *C. Fraseri*. The bulbs of this species have the same nutritive quality as those of the other."

#### HORTICULTURAL KNOWLEDGE.

ALTHOUGH I think your correspondent "SINGLE-HANDED" wrong and inconsistent in some things, as, for example, when he praises the single Buttercup and disparages the Dandelion, which are both Nature's productions, and confounds composite flowers with the double forms of the florists—still it is refreshing to meet with a writer who does not take anything for granted, or who is not ready on all occasions and without inquiry to say ditto to somebody else. We want more sceptical minds of his stamp. Such writers may occasionally deserve criticism and even ridicule, and are sure to receive both. Honest prejudice will assail them uncompromisingly; and those who are wise in their own conceit will smile benignly at what they will be pleased to regard as foibles while accepting any hints nevertheless, and acting upon them on the sly. There is a good deal of this going on in gardening as well as in other things. We want more doubters in these days. It is not enough because somebody says such and such a thing is right, to conclude that it is so.

There are numbers of garden operations advocated or recommended by noteworthy writers that are founded upon mere rule of thumb, and will not bear looking into critically. I see you assuring a doubting correspondent lately that Grapes have "without doubt" been set in a temperature of 50° min. When a matter like that is looked into one cannot help asking the question, Why should not the fruit have set? No reason has ever been furnished to the contrary. Those who recommended high temperatures had never tried any other plan. And this is only an example of horticultural teaching. Could any writer who tells us that for Grapes the heat must be kept up to from 75° to 80° by fire heat night and day respectively in the absence of sun, ever have taken cognisance of the fact that in this country Grapes set out of doors when the temperature at night often falls to 40° or lower? At one place where the writer was, the men during winter and spring had to sit up till past midnight in severe weather to keep the vinery fires burning for fear the temperature should fall below 70° or 75° in the morning; and rather than run the risk of a charge of neglect, which would have been put down to their account, I have known the men blow the glass up to the necessary point when the foreman came through in the morning, for a drop to 60° in a vinery in flower was an alarming circumstance. In that place, on the most moderate computation, I should say at least £100 was spent uselessly every year in keeping up unnecessarily high temperatures, and so never did any good but much injury to the Vines. Fancy consuming £1000 in ten years in the stoke-hole furnaces! There is no reason to suppose but that there are other practices going on now in gardens which are quite as suicidal. One man teaches them, and his unthinking pupils perpetuate them. Is not this so?—INQUIRER.

UTILISING ROSE SUCKERS.—Now that growers of standard Roses are being bothered with the Briar suckers which spring up,

will you allow me to mention a plan of utilising them? It may not be new to some of your readers, but I do not remember seeing it suggested in the *Journal*, while I have practised it for some years with considerable success. If the sucker comes from an underground eye in the stem there is no choice but to cut it off; but if, as is mostly the case, it proceeds from one of the roots a few inches from the stem, I take a sharp spade and thrust down about half-way between the sucker and the tree. If the sucker dies there is no harm done, but in nine cases out of ten it will be none the worse for the check after a day or two. A week or so after the severance I use the sucker as a stock, nip out the point, and insert a bud level with the surface of the ground; then in autumn I dig it out, carefully cut out the eyes on the stock below the inserted bud, and replant wherever I like. By this means I stop what would be an injury to my Rose trees, root-prune them, which is a benefit, and increase my stock almost at one operation without the trouble of planting Briars or of making and inserting cuttings, in both of which cases there is often a large per-centage of failures.—J. B.

### THE EFFECTS OF ELECTRICITY ON VEGETATION.

**MANURES.**—What constitutes a manure? This question is more easily asked than answered, for it is difficult to say what it is that does not act as such in one way or another. However, we may safely commence by dividing them first into two opposite classes—one acting directly as carbon food; the other, not furnishing carbon, but by chemical action stimulating the plant to a more active appropriation and assimilation. Like stone, bricks, or timber for a house, carbon is the first necessity of a plant for building up its framework and for constituting the basis of all its productions. It is commonly stated that all this carbon is derived from the atmosphere, but such a supposition originated in bygone days when vegetable physiology was little understood; yet even in these more enlightened times it still clings to us like any other bad name. It has been provided for far otherwise than that vegetation should be starved upon atmospheric carbonic acid gas. A provision exists for supplying them abundantly with carbon that has already undergone one or more stages of preparation, and thus become converted into a more suitable food. Every drop of water imbued with either vegetable or animal remains, from pond water and the boilings of vegetables up to the richest drainings of a farmyard manure heap, all convey more or less carbon food in its most acceptable form. Hence it is that green vegetables dug or ploughed into the land furnish by their juices an immediate supply of ready-prepared food, and thus constitute a rich manure. But then this superabundance of food would be of little or no avail without an additional stimulus to help its consumption; and here again we have this requirement supplied by the simultaneous decaying of its substance. It is now a well-understood fact that all additions made to a plant's growth are effected by a series of chemical changes. Then, on the other hand, these chemical changes cannot originate themselves, but are dependant upon extraneous agency—that is, by some other force applied either to the roots only, or to the roots and leaves conjointly and in adequate proportions. One of the most prominent and best understood of these resources is that of heat or warmth, and it is well known to every chemist that heat is a powerful agent in promoting chemical action; but also this chemical action in one place may produce heat or may reproduce chemical action in another place, as in the battery. In my boyhood an apprenticeship, more than half a century back, to a practical and manufacturing chemist bringing me into contact with many phenomena at that time little understood, led to a closer investigation than ordinary rule-of-thumb processes were usually accorded; and finding it stated by Sir Humphry Davy that acids combined with alkalis because they were in opposite states of electricity, one negative and the other positive, it was at once felt that herein existed a law which underlies the whole matter of chemical combinations, and rendered that which otherwise could not be accounted for perfectly clear and intelligible. Subsequently Faraday decided that the chemical affinity of one substance for another and ordinary electric attractions are one and the same thing, thus indissolubly connecting the one with the other, the apparent difference being only that they occur between opposite kinds of bodies, the former soluble, the latter insoluble. Thus heat may produce electrical attractions between the solid parts of a plant, whilst at the same time it develops chemical action amongst its soluble components, and converting liquids into solids.

It must not, however, be deemed a reflection upon the then state of chemical teaching as compared with later times, since even within the last year or two a critic, whose name is constantly before the public and luxuriating in the title of F.C.S. (Fellow of the Chemical Society), commenting on some remarks of mine,

made the unwitting admission "that he was unable to see that electricity had anything to do with chemistry!" This is introduced here only because it affords a very valuable and instructive lesson. Criticism coming from anyone who may not be well up in modern physics can hardly merit attention, and as considerable pains have been taken to give corroborative fact as far as possible, any disputed points will have to be settled between these harmonising evidences and the unsatisfied critic.

It is thus by the reciprocal effects of these chemical actions and electrical attractions that the purely chemical substances deserve the title of manures—that is, not by any direct food to the plant, but by their chemical changes developing force which acts on the plant by induction. Dip a piece of quicklime into a solution of sulphate of ammonia, and it will instantaneously afford a strong ammoniacal effluvia. A piece of fresh-made mortar will act in the same way, but the older and milder the mortar the slower will be its action. Again, any carbonate or other salt of lime will be equally decomposed by the sulphuric acid composing the sulphate, and a sulphate of lime will be the result, the ammonia disappearing; hence it is that decayed leaf mould, which derives its great superiority as a rich soil from the abundance of its raphides or oxalate of lime crystals, responds so effectually to the application of sulphate of ammonia to whatever plants may be growing therein. In this way crushed or dissolved bones become more active when combined with this sulphate, but then the latter must be in weak solution. Now, were the lime so appearing within the texture of plants in the same form or composition as when applied to the roots, there would then be some appearance of reason in its being supposed to be simply absorbed or taken in mechanically; but such is not the case. The raphides are purely a vegetable combination and construction, and play a most important part in the economy of plant-formation, and one hitherto but little regarded. They in a great measure serve the same purpose as the bones and shells of animals in giving stiffness and support to the softer tissues; and whilst, with but only one known exception in the *Welwitschia*, an anomalous plant altogether, these lime crystals always form an internal skeleton, just as silex or flint occupies the external surface of straw and canes, &c., for the same purpose—namely, to give rigidity and strength for the support of a slender and delicate stem. Lime and silex are therefore indispensable ingredients of the soil for the respective classes, and are not merely accidentally present in the plant as might be supposed, but they indicate also some special action in being thus dealt with. It is an indisputable fact that lime in its caustic state, or as lime water, is not adapted for appropriation by vegetable forms, but that it must be in combination with some other agent to enable it to be decomposed, and to have one of its elements sent one way and the other rejected or driven off in the opposite direction to form a balance, and this rule holds good with every other substance of a like kind. Now this resolves itself into what is commonly termed "root action." It is this electrolysis process that enables the plant to select its food. It is the effect of the electro-polar action taking place between the roots and the soil on the one hand, and between the stems and leaves and the atmosphere on the other. Hence, should these relative conditions be in an enfeebled state this decomposition could not be effected, and hence the caution to be exercised in the application of stimulating appliances. Let the plants be first well syringed or watered overhead until freshened, and half an hour afterwards such applications may be made with safety and benefit. Such compounds as the sulphate and urate of ammonia, nitrates of soda and potash, chloride of ammonium or sal-ammoniac, nitrate of ammonia, chloride of sodium or common table salt, &c., all act partly by the force liberated in their decomposition and partly by their moisture-attracting propensities, keeping the surface of the soil damp, and promoting the polar action between the earth and its superincumbent atmosphere. Let any damp cold frame with a northern aspect have its floor sprinkled with common table salt and closely shut up for the night, and the probability is that on the following morning the whole interior will feel warm and comfortable in comparison with what it previously had been.

Pour a little cold water over some fresh-burnt lime, and it will soon become too hot to hold. The heat here, however, is partly due to a decrease in bulk of the water in entering into combination with the lime as well as to the chemical action, but it thus serves to warm cold lands. Burnt earth and fresh coal cinder dust, also, by entering in the same way into combination with water, oxygen, and carbonic acid, furnish "force" so as to be serviceable as manures, as well as benefiting the texture of the soil.

Hitherto we have been putting the case as one of "food without appetite and of appetite without food," but we now come to the

consideration of those materials which supply at the same time both the nourishment and the appetite for promoting its consumption. Notably among these are guano, night soil, and other manures, which contain a variety of chemical ingredients as well as of organic remains consisting of albuminous compounds. Ammonia is, however, probably one of the most important elements, and which superiority is commonly supposed to arise from its affording nitrogen; but the more likely reason is that albumen is slightly soluble in its solution; hence, soot added to decayed stable manure makes a far more efficient liquid manure than when the latter is used alone, and probably this would be more generally made use of were it not for the difficulty and unpleasantness of its preparation; yet, if the following plan be adopted these nuisances will all disappear, as I have experienced for years past. For a cask of any dimensions take a common cheap skep, such as are made to encase one, two, or three-gallon stone bottles, or any other that will just enter the former and hold a few spadefuls of manure. Put in first a spadeful of manure and pack it closely down to the bottom and around the sides, so as to form a cavity that will hold a pint or more of good soot from the top of

a chimney where coal fires are burnt; next add another layer of manure, pressing it close round the sides as before, then more soot, and so on until full, when a plate or tile should be placed upon the top to prevent it floating. Now insert this in the cask, supporting it by a rod through the handles resting on the edge of the cask, and fill up with water; let it remain for three or four days, lifting it out a few times during the interval to drain; then lift it out altogether, and support it on two sticks across the top, and pour a few canfuls of fresh water to wash out by displacement the manure left in it, and when sufficiently drained the contents may go back to the manure heap for further decomposition, or may be made use of in any other way.

The solution thus obtained forms the "stockpot," and may be diluted to any extent according to circumstances. It may be used either alone of almost any strength, or it may be further enriched by the addition of about a teaspoonful of sulphate of ammonia to each gallon of liquid. Or, on the other hand, a very good substitute for guano will be formed by introducing a solution of chloride of lime in the place of the ammonia. The chloride solution is made by adding 2 ozs. of the dry powder to a wine bottle (24 ozs.)

Fig. 113.—TAJ GARDENS, AGRA.

of water, shaking well up several times before using. From one-half to an ounce of this liquid to be added to each gallon and given to Stocks, Primulas, Primroses, and numerous other soft-stemmed plants, will be found highly efficacious.—W. K. BRIDGMAN, *Norwich*.

#### THE TAJ GARDENS, AGRA, INDIA.

WE have been favoured with views and a brief description of the Taj Gardens in the city of Agra, which was originally the capital of the Mogul Empire, one of which, known as the Locust View, is represented in the annexed engraving.

The Taj Garden contains fifteen acres of cultivable ground. Many vistas have been made during the last few years. Ten years ago nearly the whole of it was in the native style, in fact little better than a native market fruit garden. Eight plots, containing nine-tenths of an acre each, have been cleared and converted into ornamental garden, which is being kept up at very little more expense than the former native style. The fruit revenue has suffered to some extent, but not much, as the best fruit has been left. There are about four hundred varieties of choice Roses

planted by Mr. Smith the Superintendent, some of them not by any means old, as the following have bloomed this season—Diana, Magna Charta, Princess Beatrice, Antoine Mouton, Anna Blanchon, Pierre Guillot, Madame Ducher, Julius Finger, Souvenir d'Adolphe Thiers, Paul Neyron, Madame Maurice Kuppenheim, Madame Alexandre Bernaix, Madame Lambard, Capt. Christy, and many others too numerous to mention. A large bed of *Maréchal Niel* on rough trellises has been a pleasing sight.

This view is taken from the south-west corner of the marble platform or dam. The plants in pots on the ground are *Opuntias* of various curious kinds. The hedge in front is *Bougainvillea spectabilis*; the Palm leaf hanging over the tall Cypress is *Arenga saccharifera*; the thick dense foliage is mostly composed of *Mimusops Elengi*; the plants in tubs on the platform are *Draenas* and *Excaecarias*. The view was opened out about two years ago, and is called Locust View because a large army of locusts visited the garden. They did not fly as locusts usually do, but came marching, crept over the high walls, and ate the leaves and flowers of a large number of ornamental shrubs and creepers. In a very short time they devoured the leaves of the *Bougainvillea* which now forms the low hedge. It was perceived that this

opened out a new view of the building, and at once the hedge was lowered. The locusts marched from the east into the garden because their wings had not grown; hence they remained in the garden until they were all destroyed. Twenty men and boys were employed ten days in destroying them. They greedily ate the bark of *Cupressus sempervirens* and *Juniperus prostrata*. The naked trees and shrubs presented a curious sight; but no permanent damage was sustained, as they were soon all covered with light green new foliage.

#### FRUIT PROSPECTS IN IRELAND.

HAVING recently had the privilege of seeing the gardens of the Duke of St. Albans, Newtown Anne; Lord Donoghmore's at Knocklofty, Mr. Bagwell's at Marlfield, Mrs. Malcomson's at Minella; Mr. Kiall's, Heywood; Summerhill, Glenview, and many others within an easy radius of Clonmel, I submit the following as a fair summary of the condition of the crops:—

*Peaches*.—At Knocklofty Mr. Ryan has a superabundant crop in the several ranges indoors. He says he removed a dozen for every one left, and will hardly lose one during the stoning period. It would be difficult to find a heavier crop on a sash-covered wall than at Minella; and this, unlike other cases, is the normal state every year. Wall Peaches, without some protection in spring, cannot be said to be a success anywhere around here.

*Vines*.—Almost in every garden with which I am acquainted there is from a heavy to a fair crop, but in this locality the heavy yield is invariably on the young wood—young canes of last year brought up beside the old. As usual Black Hamburgh, Royal Muscadine, and Gros Colman are conspicuously good.

*Apples*.—Some of the heaviest crops I know are at Glenview, where at least forty of Rivers' best sorts are variously trained. The espalier system here is notably good, and hardly deserves so much neglect as is now customary. In all other cases the crop, except in a few instances where it was heavy last year, is much better than in 1880.

*Pears*.—There is hardly an exception in reference to Pears. Except something unforeseen occurs the crop will be above the average—from fan, bush, and cordon-trained trees.—W. J. M., Clonmel.

#### THE SCOTTISH PANSY SOCIETY.

THE thirty-seventh annual Exhibition of the above Society was held on the 17th inst. in the Royal Scottish Society of Arts' Hall, George Street, Edinburgh. The past winter had damaged the stock of many growers, and where the winter had not dealt unkindly the growth in many districts was late, and as a consequence the present Exhibition suffered somewhat when compared with its predecessors. The deficiency in size and general excellency was more marked in the Show varieties than in the Fancies—indeed, there were no really fine stands of the former, although in many of the leading stands there were individual blooms of fine quality. Many stands of Fancies were very good; but a noticeable fact in both sections was this, that none of the many seedlings staged were awarded certificates. We have no doubt many good flowers will be found amongst these, but the want of finish told against them as exhibited.

There were altogether seventy-four classes for Pansies or Violas, but we have noted only the chief prizes. And here it would be well to direct the Committee's attention to the difficulty there is in finding out the names of the flowers. Those that have names attached are written on a sheet of paper and left either on the stand it belongs to, or, perhaps, on a neighbouring lot, and it is necessary to wade through a list of twelve, eighteen, or twenty-four sorts to obtain the name of any striking flower, with, perhaps, four or five other devotees waiting their turn. And even worse is it in the case of the gardeners' and amateurs' classes, for there, although the want of names ought, according to the rules, to subject the delinquents to disqualification, yet scarcely a stand in these sections is to be found with names. Shows of this kind lose their greatest claim for public support if they fail to prove educational by enabling visitors to obtain through these exhibitions a knowledge of the finest cultivated varieties.

In the nurserymen's class for twenty-four Shows Messrs. Dicksons and Co., 1, Waterloo Place, Edinburgh, were first with the following varieties and seedlings—Duchess of Edinburgh, Ladyburn Rival; seedling No. 4, a dark self; seedling No. 5, a good white self; Robert Donaldson, The Mede, G. Cunningham, Mary McComb; seedling No. 10, a fine velvety self; John Borrowman, Mrs. Goodall, Pilrig Model; seedling No. 14, yellow ground, bronze belting; Mrs. Dodds, Mrs. J. Thomson, Polly Travers, Novgorod, Jenny Anderson, and Miss Jessie Foote. Mr. W. Dickson, Ladyburn, Paisley, was a good second, and Messrs. Downie & Laird, Pinkhill, third.

In the corresponding class for twenty-four Fancies Messrs. Downie and Laird occupied first place with a grand lot, conspicuous being some unnamed seedlings. Their stand contained splendid examples of these:—J. Gardiner, Mrs. E. H. Wood, Mr. Scot Plummer; seedling No. 6, a grand flower; Luck's All; Mrs. Bliss, extra; Lady Fal-mouth, fine; R. K. Mitchell, Mrs. W. Brown; seedling No. 13, fine;

Vesta, Mrs. Barrie, R. Forrester, seedling No. 18, seedling No. 19, J. B. Downie, R. Cuthbertson, Mrs. Jamieson, extra; R. K. Bliss, and Robert Laird, extra. Any Pansy fancier who is at present without any of the above must be content to consider his collection deficient. When he obtains them he will be able to hold his head up again amongst his brethren. Messrs. Dobbie & Son were second with a stand inferior to the above by many points.

In the gardeners' class for eighteen Show Pansies Mr. Borrowman, Beeslack, was first. Mr. Findlay, Lennox Castle, occupied the first position for eighteen Fancies with a fine lot; Mr. Borrowman being a good second. For the corresponding classes for amateurs only Mr. Fleming, Berwick-on-Tweed, was first, also in most of the smaller classes. This exhibitor's flowers were amongst the finest in the room. For twelve Show and twelve Fancy Pansies, open to both foregoing sections, Mr. Fleming was again first, his Show varieties telling strongly in his favour. This gentleman was also first for the same number of blooms and sections. For the best white ground Messrs. J. Cocker & Sons, Aberdeen, were first with Sunnypark Beauty; for best yellow ground, Mr. A. Borrowman with Corsair; for the best dark self, Mr. McComb with seedling Pilrig Gem; for the best white self, Mr. D. Findlay with Mrs. Goodall; for the best yellow self, Mr. Ross, Laurencekirk, with Lizzie Stuart; for the best blue self, Mr. Fleming with Sunnypark Rival; for best crimson self, Mr. D. Malcolm, Kirkintilloch, with Mauve Queen; and for the best flower in the room, Mr. McComb with the same bloom which took first as the best dark self—Pilrig Gem.

For twenty-four bunches of bedding Violas Messrs. Downie and Laird were first, also for twelve bunches of bedding Pansies. There were also classes for flower stands filled with Pansies or Violas, and also for bouquets, but these were all more of use as warning beacons than noteworthy in any other respect. Messrs. Todd & Co. of Maitland Street showed a bride's bouquet composed of white Violas very tastefully arranged. We understand the Society is in a good position financially.

#### GARDEN ARRANGEMENTS.

AGREEING with most of what is said in your article on "Shows and their Uses," on page 455, there are one or two points on which I desire to say a word. You say "It would be an unfortunate monotonous world if all gardens were arranged according to the taste of one or two individuals;" which is very true as far as the minute details of arrangements are concerned, to which the remarks probably applied, but in the larger matter of general arrangements, which affect the landscape and give special features to a place, it always appears to me that there are certain natural laws for our guidance which cannot be put aside very much without courting failure.

I have never read a book on landscape gardening, and therefore do not know what our Loudons and Reptons have to say on the subject, neither am I quite sure of what I should like to say myself; and I beg of my readers not to take it for granted that what I shall say is correct, as if I were giving instructions about the culture of some plant with which I am pretty well acquainted, but it must be taken only as the rambling thoughts of a brother learner. I know, however, that there are professed landscape gardeners in this beautiful England of ours, who either ought to be sent to another country to practise their art, or be confined to fens and bogs where there are no hills, dales, nor trees to interfere with their elaborate designs; and I would caution all proprietors to treat with suspicion any professor, however great a name he may have, who would mark for removal by spade or axe any tree or clump of trees possessing the least claim to beauty, merely for the sake of fitting in some ready-made design which he carries in his pocket or his head, and which has no special suitability for any place in particular, but which, according to his idea of taste, might with slight variations be made to accommodate itself anywhere. Possibly not much harm would come out of it if all gardens were designed according to the taste of one or two individuals, provided these were men of broad ideas; but it is the men of one idea who are to be shunned—those who would give you the same plan for a garden on a Wiltshire down as they would for one in a Lincolnshire fen. I have no sympathy with those who would banish any particular style of decoration from our gardens, for we certainly have not too much variety, but I should like to see some attention paid to the surroundings.

I suppose most people will admit that a geometrical garden among the gravestones of a churchyard would not be in good taste; yet if you teach this practice to everybody you will have made some advance, for I saw one such some two or three years ago, and some people were looking on evidently in admiration. I do not suppose this was planned by a great professor, but I have seen proposals from men who have made themselves a name, which I think are quite as destitute of taste. For instance, I know of a splendid mansion some three centuries old, which unfortunately, like most other mansions of that age, stands in a hollow, and on one side which is the best decorated and may be

called the front, though the entrance is not there. The space is rather limited owing to a hill a short distance and an intervening stream. The hill is abundantly clothed with splendid timber, and the stream was treated by the master hand of "Capability" Brown, which is saying enough to convince most people it was made the most of. So far, then, I think the main features cannot be improved, but there are details in the arrangements between the stream and the house which do not satisfy everybody, including the noble proprietor and a much smaller individual who has the honour of being employed by the said noble proprietor to grow his Cabbages and Geraniums. The smaller individual recommends a clean sweep of flower beds and gravel walks on that side in order to show as much greensward as possible, broken here and there by suitable trees and shrubs. This, he maintains, would apparently give more space and add dignity to the two noble features already mentioned—the timber-covered hill and the winding stream. And what do you think was proposed by a great professor of landscape gardening, who was entertained by the proprietor a whole week that he might become familiar with the peculiarities of the place? The ground was surveyed, and a very elaborate plan was prepared containing magnificent temples, statuary, balustrades, terraces, and geometrical flower beds—all very beautiful no doubt, and possibly in harmony with the style of the mansion, but totally disregarding all the beautiful natural features of the place, and which could easily have been planned in London or elsewhere with no other help than a photograph of the house.

I believe, and I shall be glad to be corrected if wrong, that a geometrical garden is not suitable to have near a mansion which stands on the lower part of undulating ground, and that whenever any kind of formal decoration is used in such grounds it should be quite enclosed, so that it can be enjoyed by those who like it without being a blot on an otherwise beautiful landscape. On the other hand, when a mansion stands on high ground there is no difficulty in having as much formality as anyone can desire without spoiling the picture in the least, if it is handled by a real artist in the profession.—WM. TAYLOR.

#### UNHEATED HOUSES FOR FRUIT.

"A SURREY PHYSICIAN" at the close of his excellent article on page 480, suggests that cheap structures might be erected with the object of rendering fruit culture under glass remunerative. There is no doubt that this may be accomplished with a fair amount of success in the southern counties and in sheltered localities; but the erection of unheated structures on high elevations in the colder districts of this country would probably end in considerable disappointment. These deductions are arrived at not by reasoning alone, but by observation. I have seen in Messrs. Rivers' establishment at Sawbridgeworth large cheaply-erected houses—mere sheds covered with glass—and they were sufficient for insuring valuable crops of fruit of Peaches, Nectarines, Cherries, Pears, and Grapes. There can be little doubt that those houses have answered the purpose as well as if the cost of erection had been five times greater, and they must have proved highly remunerative. What has been done in Mr. Rivers' nursery in Hertfordshire may, it is reasonable to suppose, be accomplished in other places equally well situated; but it is another thing to apply the same system to much colder, higher, and more exposed positions in the northern counties. Large structures have been erected in Yorkshire for the purpose of insuring crops of Peaches and Nectarines without the aid of artificial heat, and after years of failure boilers and hot-water pipes have been found an absolute necessity. The system suggested by your correspondent is no doubt quite practicable in the county in which he resides, as well as in many others; but as the *Journal* circulates widely, it appears to be necessary to suggest to those less favourably situated to act cautiously in incurring the expense of erecting glass structures, unless they are also prepared to afford the means of excluding frost from them, for otherwise they will almost certainly invite disappointment instead of reaping a reward.—A TRAVELLER.

#### NOTES FOR AMATEURS.

THE following notes will be found of advantage by many amateurs, as at the present time there are numerous operations requiring immediate attention.

**STOPPING PLANTS.**—Amateurs often contrast their tall slender specimens of many kinds of plants with the compact bushy specimens grown by professional gardeners. The mystery is easily explained: Few plants are naturally bushy in habit, the majority requiring to be either frequently pruned or pinched back.

The former operation is performed after resting the plants and ripening their growth, and usually just prior to their being started afresh. The pruning alone is not sufficient to make good specimens, but to properly balance the growth all those shoots inclined to outgrow the remainder must be freely pinched back. From these will result a greater number of less vigorous growths, and in addition to this the stopping will encourage the growth of those weaker unstopped shoots which would otherwise be overgrown. These remarks are especially applicable to Pelargoniums of all kinds, Fuchsias, Eupatoriums, Solanums, Lemon-scented Verbenas, Bouvardias, Sparmannias, Veronicas, Plumbagos, of greenhouse plants; and among stove plants to Gardenias, Vincas, Asclepias, Bougainvilleas, Eranthemums, Justicias, Centropogons, and a few others. The finger and thumb must, if good plants are desired, be also freely used in the case of numbers of spring-struck plants such as Salvias, Pelargoniums, Fuchsias, Coleuses, Heliotropes, Begonias (tuberous-rooted kinds excepted), Crotons, and any young plants of the above-mentioned kinds. Pinching-back, however, must not be practised for too long a period, especially if sufficient root room to support a large head cannot be given. As a rule a well-balanced head consisting of a few strong shoots give the best results, and it is even advisable to completely remove much of the inner weakly growth. Another and very frequent cause of tall slender growth is the habit many have of indiscriminately crowding their plants, forgetting or being perhaps unaware that a few well-grown plants give much the better results.

To properly prepare for winter flowering, and also to give room for the development of Begonias, Gloxinias, Coleuses, Balsams, Fuchsias, and Cockscombs, it is advisable to plunge or stand the following in a warm position outside. Solanums, Eupatoriums, Sparmannias, Zonal Pelargoniums, Browallia elata, Salvias, Carnations, Roses, Spiræas, Deutzias (these should not have a very hot position), and Callas.

**BALSAMS.**—These, if creditable specimens are required, should not be allowed to become root-bound in the earlier stages of growth, and should also be grown as near the glass as possible. They succeed admirably in a frame on a partially spent hotbed, syringing to keep down red spider, and closing about 4 P.M. Plants in 4-inch pots or of less size may be shifted into either 8 or 10-inch sizes, potting deeply up to the first side shoots if possible, and these will then emit roots at their base. A rough rich loamy soil suits them, and a liberal top-dressing of manure should be given later on. The side shoots may be lightly tied down to short stakes inserted round the sides of the pots, and it is advisable to remove the first few blooms. Balsams when well established require abundance of water at the roots, and are much benefited by occasional supplies of liquid manure. Sturdy floriferous plants are often exhibited by cottagers which are grown entirely outside. Seed may still be sown.

**COCKSCOMBS.**—These also succeed admirably in frames with a little bottom heat, or they may be grown on shelves near the glass, but they are seldom grown to a good size in a cool house. The seedlings should be shifted into 5-inch pots, and from these again into 10-inch pots, but the final potting should be delayed till the head is forming, when the best may be selected. A rich and rather light loamy soil will suit them well, and they may be potted deeply, thereby reducing their heights, and the stems will emit roots freely.

**BROWALLIA ELATA.**—This pretty blue-flowering plant is most easily grown, and may be had in bloom either in the autumn or during the winter if the house can be kept slightly above the ordinary greenhouse temperature. Prick out the seedlings into small pots, and when well established pinch out their heads, and when breaking afresh shift into 6-inch pots. Any rather rich soil will suit them, and during the summer they should be placed outside, be pinched back till a good head is formed, and be regularly supplied with water. For late flowering, seed may yet be sown.

**CHIRYSANTHEMUMS.**—If these have not received their final potting let them be shifted into 9 to 12-inch pots at once; to the rich loamy soil may be added a sprinkling of soot, pounded oyster shells, or crushed bones. When potting allow space for a good top-dressing later on. The plants are best grown in a sunny open position and not plunged. Some of the best blooms are obtained from plants grown in a single row along the kitchen garden paths. They require much water in these positions, but the growth made is of a superior character. Those intended to form dwarf specimens must be kept stopped and trained. The finest blooms are obtained from plants grown with a single stem, these being staked and allowed to grow freely, and either stopped when 2 or 3 feet high, or allowed to grow to their natural height, when they will produce three shoots, the number aimed at in either instance.

all lower side shoots being removed. Chrysanthemums can be readily lifted from the open ground, and the young plants may, to save labour, be planted out in a good open border. If kept pinched back during this month good specimens may eventually be lifted for flowering, with perhaps the loss only of a few lower leaves.

**CARNATIONS.**—The Tree or perpetual-flowering varieties of these are of great value for winter flowering. Old plants are not retained by good growers, the young plants from autumn or spring-struck cuttings giving better results. These, when well established in small pots, may be transferred to 8-inch or 10-inch pots, and be grown for a time in a cold frame, and afterwards in the open. They should not be stopped in any way; the central growth, and later on the principal side shoots, being supported with stakes.

#### GARDEN TENTS.

TENTS and marquees are prominent features at horticultural and agricultural shows, as is indicated by the oft-employed term

in reference to the displays—"a great show of canvas." Tents are perhaps the oldest of habitations, yet this ancient mode of shelter has also become a modern necessity during the summer months, and a most enjoyable adjunct of the garden. Tents have of late years been in greater demand for lawns since the pleasurable and healthy garden games of croquet, lawn tennis, &c., became popular. They are made of various forms and sizes to meet all requirements, and the importance of tenting and shading materials were recognised by the Royal Horticultural Society by the offer of prizes for them at the late summer Show. In the silver medal collection of Mr. Benjamin Edgington of Duke Street, London Bridge, the new patent umbrella tent attracted much notice, and its suitability for small lawns was apparent. This tent is shown in the accompanying figures—in a closed form, showing its portability; and open with walls, the latter of course being optional. The advantages claimed by the manufacturers for this patent over the old umbrella tent are threefold—Greater simplicity of construction, superior strength and lightness, and increased facility of erection. Instead of the double set of ribs and stretchers used in the old umbrella

Fig. 114.—Umbrella Tent Closed.

Fig. 115.—Umbrella Tent with Walls.

tent, which was of precisely similar construction to any ordinary umbrella, this patent dispenses entirely with the ribs, and the tent is opened by pulling down the runner instead of pushing it up; and this can be done with ease by one person. The ample space between the lining and the outer cover forms an air-chamber of great value in warding off the heat of the sun. The pole is dropped into a socket which is let into the ground, and the tent can be altogether removed in a few minutes. Smaller and larger forms are made, more simple or more elaborate than the one represented. Another tent (see page 515), exhibited by Mr. Wm. Cains of Poole, for which a certificate of merit was granted at the same Show—also attracted notice by its novelty and utility. It is square, or nearly so, without a centre pole, and the seat and table inside are convertible into a box 2 feet by 18 by 9 inches, into which the tent and its appurtenances can be packed. It is referred to in our report of the Show on page 462, but the figure will afford a better idea of this strong, neat, and handy canvas shelter.

#### PYRETHRUMS, SINGLE AND DOUBLE.

YOUR correspondent "SINGLE-HANDED" since he published his celebrated protest against double flowers ought to feel himself

highly honoured, for not in the *Journal of Horticulture* alone have his remarks been criticised, and generally with considerable ability, also in a manner that makes even adverse criticism welcome to all, and nearly always instructive. The champion of single flowers will find his task a difficult one if he hopes to turn the tide against Roses as they are shown at the great exhibitions, and he will not find it easy to make the majority of people believe that single Hollyhocks, Asters, Marigolds, Chrysanthemums, &c., are more beautiful than the double forms; while, on the other hand, his opponents do not appear to clamour for double Auriculas, Polyanthus, Phloxes, Pansies, Verbenas, Calceolarias, Gladioli, and Orchids.

The general position of "SINGLE-HANDED" has not yet been seriously shaken. A vast number of ardent lovers of flowers entertain strong opinions that there is too much formalism in the ideal of the advanced florists, and they will not be bound by their rigid rules either as applied to double flowers or single. Nature produces double flowers no doubt, just as she occasionally produces lambs with two tails and calves with two heads; but there are people who will not admire monstrosities either in the vegetable or animal kingdom. But to the Pyrethrums.

If your correspondent was at South Kensington on the occasion of the great Show there he would rejoice in a triumph, for

he would see that the single Pyrethrums had far more admirers than the doubles, and in all probability the orders booked for the former trebled those of the latter, just as a great plant-manufacturer could not produce single Dahlias fast enough this spring, while the doubles were comparatively uncalled for. This may be adjudged an expression of bad taste, perhaps, by certain florists; but we must accept facts, cherish freedom, and respect the judgment of the majority. This as regards Pyrethrums was undoubtedly in favour of the single flowers, which is not to be wondered at, for their colours were far more brilliant than those of the doubles.

There is further a great variety of single forms. A select few were named by "L. C." last week, but they will not be sufficient for many cultivators, who without an extravagant outlay can have quite a good collection for the adornment of their borders and the decoration of their rooms. Such a collection is the following, selected from the varieties in Messrs. Kelway's nurseries at Langport:—Albion, pure white; Amy Hare, amaranth; Calphurina, French white; Cybele, French white; Coningsby, carmine; Corelle, cherry rose; Crimson Gem, deep crimson; Dorothy Compton, flesh; Duke of Albany, cherry red; Foix, rose, white ring roundstamens; General Roberts, crimson scarlet; Homerus, crimson and white mottled; Juno, rosy lilac; Magnoletti, white, tinged flesh; Mercury, rose; Mrs. Laxton, violet crimson; Romeo, scarlet; Roscius, pink; Rosy Morn, cherry rose; Sir Jos. Porter, bright carmine; Sirdar, carmine; Speciosissima, amethyst; Thos. Carlyle, purple crimson; Triumphans, rosy purple; Village Maid, pale flesh; Vivian, cerise; Zanetta, flesh; and Zarita, carmine rose.

Still so fine are the doubles that they may well be grown by all, and will be grown by many, therefore a few choice varieties are submitted:—Lady Derby, silvery flesh; Rembrandt, rosy purple; Capt. Boyton, crimson scarlet; Capt. Nares, bright crimson; Princess de Metternich, white; Mont Blanc, pure white; Cleopatra, yellow and white; Duchess of Edinburgh, mauve; Solfaterre, cream; Madame Billard, white, tinged rose; Minerva, rose; Vance, cream, tinged flesh; Kreimhilda, peach, tinged yellow; and Flaccida, peach.

The varieties above named all possess merit, but in the race for popularity I believe the single flowers will win. I shall grow both, for I belong to the majority, and can enjoy possibly what an orthodox florist would despise; yet my "ragged" flowers probably afford me as much satisfaction as he derives from his symmetrical blooms.—A FREE FLORIST.

#### HARDY FRUIT GARDEN.

It is of the greatest importance to keep fruit trees trained to walls or otherwise, free from insects, which during a dry cold season such as the present has hitherto not been an easy task. To facilitate the operation the foreright and other unnecessary shoots on trained trees should be cut back so as to form spurs, or be removed altogether as may be considered expedient. In most instances the spray will be more infested with aphides than the older leaves at the base of the shoots, therefore by removing those parts much is effected towards the destruction of the insects if the shoots are at once collected and burned, whilst light and air are admitted for the early formation and maturation of fruitful spurs. The removal of the shoots also better admits of the application of an insecticide, advantage being taken of a calm afternoon to promptly apply it where necessary. One thorough application is worth many partial dressings; and for destroying some insects, particularly the black aphid infesting Cherries, the brown infesting Peach trees, and the blue aphid that attacks Plums, it is necessary to thoroughly reach the pests, for unless the insects are in some way disturbed the liquid passes from them without having any effect whatever. Ensconced as the insects are under the young leaves, it is a good plan to rub the foliage with the fingers wetted repeatedly in the insecticide, following immediately with a heavy application from the garden engine. This should be followed in a day or two with a thorough cleansing with water, repeating as necessary; for frequent syringings in dry weather not only have a cleansing effect, but are beneficial to the foliage and advancing fruit.

Attend to nailing or tying-in the leading shoots, and nails and other obstructions likely to interfere with the development of the growing fruit should be removed. The fruit, especially Apricots, should have a final thinning if necessary. The long-continued dry weather has been favourable to the leaf-rolling caterpillars on fruit trees, and for this careful hand-picking is the most effectual remedy. Pyramid, bush, and espalier Apples, Pears, Plums, &c., may be stopped and have superfluous growths removed where necessary, not stopping closer than to three or four buds, as, if cut-in too hard, the trees will probably start into second growth without forming fruit buds or spurs. Where the fruit is thick lose no time in judiciously thinning the crop; a too heavy crop causes inferiority of the present fruit, and inevitably results in a future failure.

Bush fruits, such as Gooseberries, with Red and White Currants, should also have the shoots stopped when the growth is over-abundant, but the crops generally are so heavy that less growth than

Fig. 116.—Cains' Portable Tent. (See page 514.)

usual has taken place this year. In order to secure fine fruit for dessert the crop should be thinned, so that when ripe the fruits hang clear of each other. There is no comparison between the ripe fruit from trees carrying a too heavy crop and those with a moderate one in point of quality. Strawberry plants should have been mulched some time since, and will now require to be carefully netted to protect the ripening fruit from birds. Mulching will have been found valuable where it has been resorted to, for fruit trees of all kinds, and especially Raspberries, which are suffering from lack of moisture, as also are fruit trees in restricted borders, which should when necessary be well watered.

#### FRUIT HOUSES.

*Pines.*—When the fruit commences colouring cease syringing the plants, and to improve both its colour and quality freer ventilation will be very beneficial, but not admitting air so as to reduce the temperature in the daytime below 80°, maintaining the night temperature at 70° to 75°; and although the quantity of moisture in the house is to be gradually diminished, the water at the roots must not be unduly restricted. Plants started into fruit in February will, as regards Queens and Providence, ripen this month; but Smooth Cayennes, Charlotte Rothschild, and similar kinds will not be ripe for three or four weeks, so that a good successional supply may be secured by those varieties, the period being still further extended by removing some of the fruiting plants to a cool airy house. Under ordinary circumstances fire heat should now be discontinued, except for providing the temperature at the roots at 80° to 90°, and to accelerate plants with fruit in an advanced condition of growth. For successional stock such heat will be no longer necessary, as the temperature by reason of the assistance which is obtained from the heated beds rarely falls below 65° at night, and this temperature is most suitable for the satisfactory development of the plants. As they will make growth rapidly care should be exercised in the management, especially in ventilation, so as to avoid an attenuated state

of growth. On fine mornings admit air at 75°, gradually increasing until the temperature reaches 85°, when the top and front lights should be opened as wide as is necessary, diminishing the ventilation in the afternoon by degrees to about 80°, at which close, giving the plants a light sprinkling with the syringe daily when sunny weather prevails. From the stock of suckers on the early section of fruiting plants a sufficient number to meet the demand should be taken off and started at once to afford stock for fruiting about this time next season and onwards, forming a supplementary batch to those which were started last March, treating them similarly; only if the soil be dry water must be afforded at once, and the shading will require to be more effectual.

*Cherry House.*—Abstention from syringing during the process of the fruit ripening and its preservation favours the increase of red spider; therefore, so soon as all the Cherries are gathered no effort should be spared to eradicate the pest by means of syringing twice a day. The roof lights may be removed altogether when the fruit is all gathered, but before doing so it is well to see that there are no black aphides, and if there be any destroy them by frequent fumigation. There must be no lack of moisture at the roots, as it is important the buds be well plumped for next season's fruiting, and unless the soil is moist they will not develop or mature properly.

*Peaches and Nectarines.*—In the earliest forced house the fruit is off the early varieties, also such kinds as Royal George, Grosse Mignonne, and Noblesse; and when this is effected the trees must be cleared of insects by employing the syringe freely, and if necessary an insecticide, as it is of the greatest importance that the foliage be kept clean and healthy to the last. There is a danger in early forced trees, especially those some years subjected to the process, of the buds becoming over-developed, so that they start into flower prematurely. This can only be remedied by admitting all the air possible; and where possible, as should always be the case with forced trees, the roof lights should be removed so as to afford the trees the benefit not only of rains but of night dews, which tend in a measure to compensate for the strain upon the trees in the earlier stages of growth. The wood not required for bearing next season should be cut out as well as that having borne fruit this season, unless it be wood necessary for the extension of the trees; and if there be any weak shoots thin them well out if there is a sufficiency of vigorous growth to replace them. In any case thin out so that every leaf can have full exposure to light and air. In the house started early in the year the fruit will, as regards the early varieties, be ripe, and the trees must be treated as above advised as regards syringing and cutting out this year's bearing wood, as well as thinning out where required. Spray should be kept well in hand by pinching, and on no account must the trees lack moisture at the roots.

As the fruit commences ripening in succession houses cease syringing, but maintain a moderate degree of moisture in the house by damping the border and paths occasionally, and affording, under favourable conditions, a free circulation of air. Fire heat may under most circumstances be dispensed with, except where it is desirable to accelerate the ripening of the crop. Suitable temperatures for ripening fruit are 60° to 65° at night, and 70° to 75° by day, with an advance to 80° or 85° from sun heat. Attend to former directions respecting succession and late houses in tying and regulating the shoots, and lose no opportunity of ventilating freely. Avoid overcrowding, and shorten or remove any leaves that shade the fruits, which will then colour well. Maintain the borders both inside and outside in a proper condition as to moisture, and mulch with about a couple of inches thickness of short manure.

#### PLANT HOUSES.

*Orchids.*—Examine the East Indian species, and any that have grown vigorously and filled their pots with roots should be shifted. If the roots are attached to the pots, instead of striving to remove them break the pot, allowing the pieces to remain attached to the roots. Do not afford large pots, as the majority of Orchids derive their support mainly from the atmosphere. Any not requiring potting will probably need a top-dressing of fresh sphagnum. Plants on decaying blocks should be placed on new blocks at once, so as to afford time for making new roots before the season of rest.

All East Indian Orchids and Dendrobiums syringe frequently, especially on fine days. Aerides, Phalænopsis, Saccolabiums, and Vandas should not be removed from their growing quarters, except for a few days, otherwise the plants as well as the flowers will suffer. Any plants with the growth approaching maturity should have a lessened supply of moisture, and be more exposed to light and air, so as to gradually induce a state of rest. Cypripediums require watering and syringing freely, and if the house is damped with liquid manure once or twice a week it will have an invigorating tendency. The Cattleya house will need only sufficient shade to prevent scorching, increasing the ventilation. In order to prolong the flowering period of Cattleyas and Lælias, remove them to a dry house. Miltonias that have their growths completed must be removed to a cool house, and only have sufficient water to prevent the bulbs shrivelling. Thrips are very troublesome at this season of the year; the houses should be frequently fumigated, as this insect is not easily killed even in its young state. Do not allow water to remain for days together in the base of the young shoots, especially in cool houses, or they will be injured, and in many instances decay.

*Stove.*—The sun having now attained its maximum power, fire heat can be dispensed with if the weather is hot; but if necessary the fires must be continued to prevent the temperature falling below 65° in the morning, and to maintain it at 70° to 75° by day. Insects increase rapidly at this season, and unless prompt means are taken for their destruction they do irreparable mischief, both disfiguring the plants now and injuring them for the year to come.

## THE BEE-KEEPER.

### A SEARCH FOR APIS DORSATA.

[EXTRACT from a letter by Frank Benton, from the *Bienenzeitung*, communicated by Alfred Neighbour.]

"Batavia, 16th March, 1881.

"You have no doubt been anxiously waiting to hear from me. I wish I were able to send you some news of a more satisfactory character to-day, but . . . I can hardly describe to you what exertion and trouble I have been obliged to go through, and how much I have travelled by land and sea in order to discover the whereabouts of this wonderful insect of the East Indies. I am now about leaving Java without having seen a single specimen of these bees. I did not succeed in meeting with any during my five-weeks stay here, though I looked for them wherever I considered it possible to discover them—in the interior of the island, on the high mountains, in the highlands, and in the plains—in fact, in every place where trees were to be found. I have spoken to many of the natives who knew something of these bees, although few had ever seen them; but I did not meet with a single European who had ever seen *Apis dorsata* in Java. I went to West Java, and thence into the interior of the island, whence I returned to Batavia. I took the steamer to the eastern ports of the island, and thence made excursions into the country. At times I was accompanied in my search for these bees by as many as ten men, all natives of the island, whose usual occupation was to search for wild bees in order to deprive them of their honey and wax. All these men I paid well, and they in return did their best to find these bees. I offered to give a sovereign to the man who would show me the first colony, and, of course, everyone was anxious to earn this money, a sovereign being looked upon as a large sum by the common people of the island. I also agreed to make the discoverer of the second colony a present of half-a-sovereign in addition to his pay, but all to no purpose. I was not even fortunate enough to find a single bee of the *dorsata*.

"My present plan is to return *via* Ceylon, and in case I do not succeed in obtaining a number of colonies of *Apis dorsata* there to proceed by steamer to Calcutta or Bombay. I am convinced these bees are to be found in Ceylon, where I learnt on the evening of my departure the whereabouts of the *dorsata*, but I do not know in what quantities they are to be obtained there. I took a number of Cyprian and Palestine bees with me, on which a good deal of my time was spent. Several colonies were left in Ceylon, and in the beginning of February I arrived at Batavia with ten stocks of Cyprian and Palestine bees. These were sold to the Government, and are now in the grounds of the School of Agriculture in Buitenzorg, where they are doing well. They have been in my charge till now, and will in future be attended to by one of the masters of the school.

"Mr. Bykens, who took out some colonies of bees to Java for the Dutch Government, has returned to Holland. The few stocks which were alive when they reached Java died soon after. Mr. Bykens

started with twenty-eight colonies, five of which only survived the voyage to Java, and these were in a very weak state. Although he spent nearly three years in Buitenzorg he took no steps whatever to discover *Apis dorsata*. His first attempt, though a most expensive one, has turned out a complete failure; the bees were brought all the way from Holland, while they might have been obtained equally well much nearer Java. Jaffa, which is only twelve hours' voyage from Port Said, would have supplied them. It was further unnecessary to have a separate cabin of 10 feet square for the bees, as they would have been quite as well on deck under cover of a sail, which would have saved 250*fl.* In addition to the cabin a certain quantity of ice was used daily to keep the colonies cool—a proceeding which, besides being expensive, was absolutely injurious to the bees, as it rendered the hives damp, and caused dysentery among the population. During the whole voyage the bees had only one opportunity, at Port Said, of leaving the hive; it would have been much better to have sent them *via* Ceylon, and to have allowed them to remain there for a time.

"It is almost impossible to get an interpreter on the island of Java, and I therefore set to work to learn Malay enough for my purpose; in the meantime the Director of the Department of Public Instruction has placed at my disposal the services of a half-caste Malay who speaks a little Dutch; the Malay language, however, is so easy that I was soon able to get on.

"In the Singapore Museum I saw two combs of *Apis dorsata*; one was 2 feet in length and width, the other 3½ feet, and the parts which had been used for breeding were 1½ inch thick. A square inch contains about twenty cells, from which we may conclude that *Apis dorsata* is seven-eighths of an inch long, and is a comparatively more slender bee than ours. The two combs were still attached to pieces of the branches of the trees, from which they had been suspended in a perpendicular direction. Many credible persons who have seen *Apis dorsata* in the forests confirm the opinion I have always held, that the position of the combs which these bees construct is perpendicular and not horizontal, as maintained by Mr. Dathe and others (see 'Dathe's Directions for Breeding Foreign Races of Bees,' pages 4 to 6).

"It is my firm belief that it is possible to domesticate *Apis dorsata*, and that this bee will prove a valuable acquisition.

"The reports of the quantities of wax and honey said to have been obtained from *Apis dorsata* are simply marvellous. You will hardly credit the statement that thirty natives were laden with honey and wax taken from the bees on one tree, and yet its correctness is vouched for by a trustworthy person who had seen these bee-hunters himself. From Bombay, Calcutta, Bengal, and Timor large quantities of wax are exported to other parts of the East Indies, chiefly to Java, where, according to reliable information, the consumption of wax amounts in value to about 2,000,000 rupees annually. It is chiefly used for polishing furniture and in dyeing the textile fabrics of the natives, the wax being spread over certain portions of the articles, while the unprotected parts are acted on by the dye.

"I start for Singapore to-morrow, and after a short stay there I shall proceed to Ceylon.\*

"Yours truly,  
" (Signed) FRANK BENTON."

The above letter is a valuable one as regards the history of bee-keeping. It affirms that Mr. Benton introduced *Apis mellifica* not only into Ceylon but also in Java, and it further states that Mr. Bykens' attempt has proved a failure.

*Trieste, 20th April, 1881.* (Signed) A. SCHRÖDER, JUN.

## HOW TO MAKE MOST OF A STOCK IN A STRAW SKEP.

In a former article to this Journal I mentioned a plan of stocking bar-frame hives from skeps, further details of which have been so frequently solicited that I take this opportunity of describing the practice in full. We are supposed to have a good stock in a skep or box which we desire in the simplest way to utilise mainly for increase, such increase to be in the form of bar-frame stocks. Of course any number of stocks may be similarly treated, but for simplicity we shall only take the case of one.

During the spring months it may be supposed to have been fed and attended to so as to encourage early breeding, and that it is now in a crowded state. A bar-frame hive—a mere box with frames and floorboard will do temporarily—is prepared thus:—Five or six of the frames are filled in the usual manner with comb foundation and arranged at proper distances in the centre of the hive. Close-fitting division boards enclose the space these occupy, outside which either empty or sheeted frames are in-

\* *Apis dorsata* attaches its combs perpendicularly to the highest branches of trees and against projecting rocks, and it takes no trouble to conceal them. Near the coast and in the plains *Apis dorsata* is never seen on the wing; it is only to be met with inland at a distance of some miles from the coast, where it settles in highland forests only, and at an elevation of about 1600 metres (5250 feet). It seems to me as if Mr. Benton had searched for the *dorsata* in the forests of the plains and too near the coast. In highland forests only are colonies of *Apis dorsata* to be found in considerable number, like the nests of hornets in our own country.  
(Signed) VOGEL.

serted merely to support the quilt in the meantime. For a quilt a square of any light cloth is taken the size of the hive top, and a larger square of waterproof material, such as oiled calico or enamelled cloth. Out of the centre of both a 6-inch circular hole is cut, after which they are put in position, the outer waterproof covering being tacked over the edges of the hive so as to throw off rain. The hive thus prepared is placed on the stool from which the skep has just been lifted, and the latter, after a whiff of smoke, is lifted from its floorboard and set over the frames. The old entrance is at once closed, and the floorboard with its adhering bees set sloping against the new entrance. The latter should be contracted to 2 inches or so, which will soon raise the temperature inside sufficiently to compel the bees to spread themselves downwards on the sheets of foundation. If an old sack be hung over the skep for a few days before this operation, and at once similarly hung over both the skep and its nadir, the bees will not be puzzled with the new entrance. This is the first step in the operation. Meanwhile let us note its advantages. Unless swarming were actually imminent, and in most cases even although it were, it will be averted for the time being. The superabundant population, instead of clustering idly about the entrance, is set to the useful work of drawing out the cells on the sheets of foundation—a work no way exhaustive of their energy; and a set of combs are ensured of almost perfect quality, for they are drawn out before there is any excessive heat or weight of bees to sag or curl them.

The bee-keeper must now prepare for the second stage of the operation—viz., dividing the twin stock thus formed. To make the most of his opportunity he must in some way or other get possession of a second fertile queen. No better opportunity can be found of introducing an imported Ligurian if such can be obtained. A week or longer may elapse before the crowded state of the doorway gives indication that the lower hive space is fully occupied. When this is the case the hive is gently removed to its old floorboard in a new location. The new combs are then lifted out and examined to ascertain the presence or absence of the queen. The presence of eggs and larvæ is presumptive evidence of her being on the new combs, but no doubt must be left on the subject. If neither eggs nor grubs are seen it is evidence that the stock is not ready for division, and the skep should be replaced for a few days; but if these are found in some quantity it is quite safe to make the division. The queen then must be found. If not on the new combs, and it is desired to finish the operation at once, the bees must be driven from the skep, and if open driving be practised the queen will generally be found within five or ten minutes. Taking her gently by the wings let her go under the quilt of the frame hive. Replace the eut quilts by a whole one, and cover with some sort of roof. The driven bees should all be returned to the skep after settling it in its new location, and the strange queen caged for twenty-four hours under the feed hole in the top. On no account should the strange queen be given to the bees on the old stand, Mr. Cheshire's advice on page 320 notwithstanding. I never knew a queen to be molested when introduced in the way I describe, but I have seen so many instances of failure by his method that I have come to regard success by it as the exception rather than the rule. The stock on the old stand is made up largely of old bees of the warrior class, which are always suspicious of a strange queen and generally ball her. She may be liberated after being caged twenty-four hours and is apparently received with joy, but a few hours after she is found to be again balled. I have known this caging and balling go on daily for eight days. The reason is obvious. For nearly a week bees from the removed stock will daily find their way back to the old stand. Some keen instinct informs them that the queen there found is not the one they parted with a few minutes before, and a single hostile act—may be the smell of ejected poison—seems to affect the whole stock, so that the balling is repeated. But when introduced into the removed hive, especially if driving has had to be resorted to, it will be found that she is generally accepted without any suspicion, and once accepted she may be regarded as safe from any further attack. These remarks hold true of all methods of artificial swarming when a strange queen has to be introduced.

But to return to our stocks. More frames must be added to the new stock as fast as the bees can cover them, and food given if the weather is unpropitious. The skep should be left on its floorboard to recover itself for a few days, and be supplied with sweetened water to make up for the loss of its old water-carriers. So soon as it begins again to get crowded the whole operation is to be repeated. It may be regarded as good practice in an average season to get two bar-frame hives thus filled, and have a strong skep stock left; but I have known four strong new stocks thus formed and a large quantity of honey in supers taken from the earlier of these.

If it be desired to abolish the skep no queen should be given to it at the last division. Three weeks after all the bees may be driven from it to form a fed-up stock, and its contents taken for the honey. Here again I would venture a caution about queens. Twenty-one days after an artificial swarm or division, such as I have described, there ought to be a young queen in the skep. Until the combs are cut out we cannot tell whether she is fertilised or not. She may be, even though no eggs have yet been laid. It is wise, however, to arrange matters beforehand on the understanding that at the date of driving she is still unfertile. If no precaution be taken she may come forth on her love-search, as she has probably done for several days previous. Not marking her location as she did at first, she returns to look for her skep, but no skep is there—only a box, like other boxes beside it. Little wonder if she enters another skep, if such there be, or a neighbouring bar-frame hive, and is killed. To guard against this the skep should be concealed by a sack or other covering for several days before the transfer of the bees to the new hive, over which the same covering may be similarly arranged, and thus the old appearance of things preserved.—WILLIAM RAITT, *Blairgowrie*.

#### TRADE CATALOGUE RECEIVED.

Benjamin Edgington, 2, Duke Street, London Bridge.—*Illustrated Catalogue of Marquees, Tents, &c.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**The Manchester Show (W. J. M.).**—The Exhibition to which you refer opens on August 24th and continues for four days. It will be well worth a visit.

**Training Fruit Trees (Cordon).**—We shall shortly publish some notes on cordon training which we think will meet your requirements. There is no book specially devoted to the subject you name.

**Strawberries (J. E.).**—The fruit of Cockseomb is large, ovate, and sometimes cockscomb shaped; skin pale scarlet; seeds prominent; flesh white with a rosy tinge. Flavour good. Growth of plant free, yet not markedly spreading. The fruit of La Con-tante is large, conical, and regularly formed; seeds not deeply embedded; skin bright crimson; flesh white tinged with rose; flavour sprightly and rich. The plant is of compact habit, and does not produce runners so freely as some others.

**Larvæ on Grass (Pendle).**—Though it is impossible to decide positively from the specimens sent (and which are not pupæ, but larvæ shrivelled from the attacks of some parasite), the species occurring in such profusion appears to be the Antler Moth (*Chareas graminis*). Since the time of Linnaeus it has been occasionally noticed as injurious to grass lands, though more frequently seen in the moth stage during August than in its larval condition, since it is more or less subterranean during the period of growth.

**The Cucumber Disease (W. W., St. Albans).**—The form of the disease that has attacked your plants is we believe incurable, and probably the only mode to prevent a similar calamity in future will be by thoroughly cleansing and disinfecting the house and obtaining soil from another source. The Cucumber-root disease is illustrated on page 34 of this Journal, the issue of January 4th, 1875, which can be had in return for 3½d. in stamps, sent to the publisher asking him to forward No. 720. The disease as attacking the leaves and fruit is referred to in Nos. 524, 526, 529, 530, 532, 534, and 536. These numbers, or any of them, can be had at the price above quoted, 3½d. each.

**Cauliflowers Clubbed (A. S. M.).**—Letters arriving on Wednesday morning can only be answered in the briefest possible terms. So far as we understand your case the plants are beyond remedy. You might try solutions of paraffin from a quarter of an ounce of the oil to a gallon of water to such stronger doses as the plants will stand, and let us know the results. You may as well kill a few with paraffin as let them be killed by the maggot.

**Vine Leaves Injured (H. Lewis).**—We fear your Vines are attacked with the clay-coloured Vine weevil, *Curculio picipis*, which is highly destructive. It feeds on the tips of the young shoots at night, and as the leaves expand they appear as if torn and perforated. We know of no better mode of securing the beetles than spreading a sheet under the Vines at night and shaking them, or jerking the laterals sharply to displace the pest. The work, however, must be done quickly yet quietly, for the insects often fall to the ground when they are disturbed and a light approaches; and on the other hand they sometimes cling to the stems with great tenacity. If this proves to be the enemy you must tho-

roughly cleanse the Vines and house in the winter, removing the surface soil from the border, if you have such inside, and adopt every means of eradicating the pest.

**Chionodoxa Lueillæ (H. S.).**—It is a beautiful hardy bulbous plant introduced by Mr. Maw from Asia Minor a few years ago. We have not had experience as to its "ready multiplication," but should think that the bulbs would increase freely in suitable soil. You will find an illustration and full description of this plant in our issue of March 31st of the present year. If you do not possess that number it can be had from the publisher in return for 3½d. in postage stamps. The abnormal growth of your Cabbage leaf is singular, but not very unusual. We have seen very similar examples, but the cause of their production is unknown.

**Insects on Vines (G. P.).**—Your Vines are attacked with the Vine weevil, which is referred in a reply to another correspondent. It is highly destructive, and a sedulous search should be made by night as well as by day for the weevils, which must be promptly destroyed. When the Vines are at rest the rods must be well scrubbed with hot soapy water, all the woodwork of the house being washed, all the surface soil removed from the border and fresh added, all plants in the house being at the same time cleansed and repotted or top-dressed, and thus you may succeed in eradicating a dangerous enemy.

**Peach Trees Unsatisfactory (W.).**—The condition of your trees denotes some serious error in culture, but where the precise mistake is no one can tell without being acquainted with the character of the soil and trees, and the treatment to which they have been subjected. The growths may have been much overcrowded in summer, or infested with red spider or other insects; or, what is very likely, the border has not had nearly sufficient water, and the roots are in a torpid state. Examine the border at a depth of 2 feet, and probably you will find it too dry there; if not, the soil is too poor, and the roots should be raised and placed in better compost, and the surface be thickly covered with rich manure. Nearly all failures in Peach culture under glass arise from overcrowding the growths in summer, and overdryness of the border at all seasons of the year. The cause of your failure ought not to be difficult to determine, and the remedy may then be easily applied.

**Cocoa-nut Fibre Refuse (M. J. B.).**—We have not the slightest idea whether you can obtain what you require in Wales or the towns adjacent. Possibly it might be worth your while inquiring at Bristol; still, where there are only small quantities of the refuse for disposal the price is much greater than in the larger cocoa-nut mat and brush manufactories. Both the yellow and copper-coloured forms of the Austrian Briar are included in the catalogues of Messrs. Wm. Paul of Waltham Cross; George Paul, Cheshunt; Cranston, Hereford; Veitch, Chelsea; Bunyard, Maidstone; Laing, Forest Hill; and possibly in those of other Rose-growing nurserymen, which implies that this bright old species is "yet in the trade."

**Plum Trees Diseased (W. B.).**—The precise cause of the condition of trees affected similarly to those from which you send sprays is not known. The appearance, however, is an expression of debility, consequent probably on the roots having penetrated subsoil deficient in the food necessary for maintaining the health of the trees. Had the roots been kept in a healthy active state near the surface by suitable top-dressing, the trees in all probability would not be in their present unsatisfactory state.

**Grapes not Ripening (J. H., Old Subscriber).**—Without knowing some thing of the condition of your Vines, their age, character as to vigour or the reverse, and weight of the crop, it is not easy to answer your question; but this we can say, that if they are in good health and not overcropped the fruit will ripen. The maturing of the wood will not arrest the ripening process, but will aid it. The long and cold spring has retarded the swelling of the fruit considerably in all gardens, and Grapes are generally later than usual this year, just as outdoor crops are later than during favourable seasons.

**Insects in Soil (R. C.).**—The most important word in your letter appears to be "emites," and we are not sure whether you refer to mites or emmets (ants). If you mix half an ounce of paraffin with a gallon of water, agitating it violently so that the two become well incorporated, which is not easy to effect, and sprinkle the soil where the ants or mites abound, it will, we think, drive them away and not injure the roots of the plants, although it will be a wise precaution not to sprinkle the stems.

**Rose Catalogue (Rosarian).**—We are unable to inform you when the National Rose Society's catalogue will be ready. You can no doubt obtain the information from one of the Honorary Secretaries of the Society, the Rev. H. H. D'Ombain, Westwell Vicarage, Ashford, Kent; or Edward Mawley, Esq., Addiscombe House, Croydon. The Society's Southern Show will be held at the Crystal Palace on July 2nd, and the Northern Exhibition at Sheffield on July 14th. You will find a list of other Rose Shows on page 329 of our issue of April 28th.

**Peach Trees not Thriving (Inquirer).**—Your case is very similar to that of another correspondent, and the reply and advice we have given to "W." will be equally suitable for yourself. We cannot say which of the following evils have operated the most strongly in rendering your trees unsatisfactory—insufficient or injudicious ventilation, insects with overcrowding of the growths in summer, or a deficiency of water at the roots; but from what you say we think the ventilation has been defective and the water insufficient. You can judge for yourself on the point of overcrowding, according to the rule which many years of experience have proved is a sound one—namely, the leaves of one shoot should not overlap those of the next.

**Gesneriaceae Plants Unhealthy (W. S. K.).**—The plants and leaves sent have no thrips on them, nor do we think the injury arises solely from insect attacks, nor indeed chiefly. We rather attribute it to something pernicious either in the soil or water, or both. Is there iron in the soil? Try a few plants in soil from a fresh source and use only rain water. We assume that the temperature of the house has been suitable for the plants, the atmosphere kept in a proper state, and shade afforded as needed. Errors in these respects would account for the unsatisfactory state of the plants.

**Caterpillars on Holly Shoots (Mr. Brierley).**—These are the caterpillars of a small moth in the genus *Spilonota*; several of which, nearly resembling each other in the larval stage, are very destructive to buds and young shoots. Some suggest the slow process of catching the moths during the summer before they deposit eggs. These are difficult to find, being minute, and resembling in colour the buds where they are generally placed to remain unhatched through the winter. We should try the effect of syringing the shrubs with a solution of paraffin at the strength of a wineglassful of the oil to 4 gallons of water, every alternate syringe being forcibly ejected into the pail and on the trees, otherwise the oil will not be well mixed. If soapsuds are used instead of water the dressing would be more effectual, but a sediment would be left on the leaves. Or perhaps a solution of hellebore would be efficacious,

2 ozs. of the powder being mixed into a creamy paste with a little hot water, adding a gallon of cold water, then applying with a syringe. We have seldom seen such a serious attack, and strong measures will be necessary to destroy the pest. Try the hellebore mixture first.

**Tomatoes during Winter** (*P. H. S.*).—Although the temperature you will be able to maintain during the winter will be somewhat low for Tomatoes, we still think you ought to be successful; but whether the crop will be more remunerative than Mignonette we cannot venture to decide. It is quite certain the demand for Tomatoes, which rapidly increases, is during the greater part of the year still in excess of the supply, though in all probability the best prices are obtained from April to August. Vick's Criterion is well adapted for fruiting in comparatively small pots, but we should prefer a larger-fruited and more saleable variety, such as Earley's Defiance or a good selection of the Large Red. July 1st is early to either strike cuttings or sow seed to secure a stock to plant early in October, as in this case the plants must experience a very undesirable check. Sow seed or strike cuttings (one plan being as good as the other) about the first week in August, grow the plants as sturdily as possible in the open as you propose, attending closely to their requirements, and taking care to house them before cold damp weather may be anticipated. The first bunch of bloom will have set by the time it is intended to plant. Your proposed after-treatment is generally correct. Further remarks on this subject will be published in the course of a few weeks, and in the meantime you cannot err by perusing Mr. Iggulden's "Manual on the Tomato," price 1s., or 1s. 1d. post free from this office. It is a very reliable work, and treats on Tomato culture for market purposes.

**Names of Plants** (*H. S.*).—1, *Dianthus arenarius*, the Sand Pink; 2, *Reseda undata* (can you send us a small plant?); 3, *Saxifraga ceratophylla*; 4, Specimen insufficient, perhaps *Sedum acre*; 5, *Sedum rupestre* (?). (*C. P. L.*).—We have repeatedly stated that not more than six specimens should be sent to be named at one time, but as you sent such good examples and well packed, which greatly facilitate the process of identification, we make an exception in your case and publish the names of them all. It is a pleasure to name good and fresh specimens, but the identification of crushed, imperfect, and withered sprays is more tedious and difficult than many imagine. 1 and 2, *Dactylis glomerata* (Rough Cocksfoot Grass), the former a very small example; 3, *Bromus sterilis* (Barren Broom Grass); 4, *Carex laevigata* (Smooth Sedge); 5, *Bromus mollis* (Soft Broom Grass); 6, *Arrhenatherum avenaceum* (Oat-like Soft Grass); 7, *Alopecurus pratensis* (Meadow Foxtail Grass); 8, *Trisetum flavescens* (Yellow Oat Grass); 9, *Festuca duriuscula* (Common Fescue Grass); 10, *Trisetum flavescens*; 11, *Anthoxanthum odoratum* (Sweet-scented Vernal Grass); 12, *Poa pratensis* (Common Meadow Grass); 13, *Lathyrus pratensis* (Heath Peasling or Meadow Vetchling); 14, *Chrysanthemum Leucanthemum* (White-flowered Ox-eye Daisy); 15, *Saxifraga rotundifolia* (Round-leaved Saxifrage). (*H. Dod.*).—1, *Pteris cretica albo-lineata*; 2, *P. longifolia*; 3, *Adiantum pubescens*; 4, *Pteris argyrea*. (*Clonmel.*).—The name of your plant is *Clematis Vitalba*, the Traveller's Joy. (*J. W.*).—*Cattleya guttata* Leopoldi. (*Rosa.*).—1 is *Phlox Nelsoni*; the Orchid is *Oncidium sphacelatum*, and the other specimen with white flowers is *Saxifraga ceratophylla*. (*W. M.*).—It resembles *Begonia Sutherlandi*. (*Stifford.*).—1, *Cheiranthus alpinus*; 4, *Asperula odorata*. The others were too withered to be recognisable. (*W. G. L., Bath.*).—The plant is *Thalictrum aquilegifolium*, a member of the natural order Ranunculaceae. (*A. M. B.*).—The specimen with purple flowers is *Viola cornuta*, the one with yellow flowers is *Alyssum saxatile*; but the small fragment of *Stonecrop* cannot be identified. (*S. B.*).—The large flower is *Cattleya Mossiae*, and the other is *Dendrobium crepidatum*. (*X., Yorkshire.*).—1, *Helianthemum ocellatum*; 2, *Aubrietia microstyla*; 3, *Gloularia trichosanthes*; 4, *Myosotis dissitiflora splendens*; 5, *Iberis Garrethiana*. (*W. K.*).—The Veronicas are—1, *V. gentianoides*; 2, *V. pulchella*; 3, *V. rupestris*; and 4, *V. pectinata*. (*R. N.*). There are many varieties of *Helianthemum*, but yours resembles one called Beauty.

**Supers and Prevention of Swarming** (*Rector*).—The method of treating the supers depends somewhat upon their material, but the principle applies to all that they should be protected by some good non-conductor of heat. If this be neglected, in chilly weather the bees will refuse them, while in the heat of a summer's sun they will be extremely likely to swarm and leave them. The junction between hive and super should also be as perfectly closed as possible, or the air escaping so cools the brood nest that a far larger number of brooding bees will be required in the hive below. The mischief of bees swarming with half-filled supers is of more common occurrence with skeps than with properly managed frame hives, for reasons which have been lately stated in our columns. With skeps, however, eeking seasonably done will almost invariably prevent swarming, the reason apparently being that bees always carefully avoid leaving a gap between their cluster and the entrance (except during the season when enemies are not abroad), and that should a swarm leave before the eke is filled the residue would be incapable of keeping up direct communication with their hive door. The eke being finished, so great an increase of space is given to the brood nest that its crowding is permanently prevented, and so the need of colonising disappears. Eeking, although it may augment the aggregate of honey, reduces the amount of that obtainable in supers, since it is a rule, the reason for which is obvious enough, that shallow hives give more surplus above them than deep hives.

**Supering and Driving Bees** (*A. J. Brown*).—It is not too late for supering. In driving place the hive on its crown, fixing it firmly, and inverting the other hive on the top so that the two hives are placed mouth to mouth. Closely bind round the junction of the hives with towels or other material to prevent the escape of the bees, then drum the lower hive until the bees leave it and enter the storey above. The common black bee is what you have sent a small specimen.

#### COVENT GARDEN MARKET.—JUNE 22.

BUSINESS remains without material alteration. The supply of Strawberries has increased considerably during the week, and the fruit is generally of good size and colour.

#### POULTRY AND PIGEON CHRONICLE.

#### AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 477.)

As our agricultural machinery and implements are manufactured with the object of saving labour we will refer to the advantage of the elevator or stacker. To lift by bodily force the hay or sheafed corn from off the waggon on to the rick is about the heaviest and most toilsome work done on the home farm; in fact, we find but few men at the present time capable, even if willing, to perform this work, as the strongest and most willing men have left the farmers' work in search of higher wages on public works in towns and on railways. This being the case, the farmers have no alternative but to resort to labour-saving machinery or pay for inefficient manual labour at a disadvantage. Upon the home farm, if it is to be well conducted, the elevator must be employed. They are now made capable of being attached to the thrashing machine, and then elevating the straw as fast as thrashed on to a rick at any height up to 25 feet, and delivered from the thrasher at any angle. They are, however, capable of being used by horse gear, so that in building either hay or corn stacks they are available in the fields wherever the ricks may be required.

We must also refer to Clayton & Shuttleworth's portable steam-power chaff-cutter, which as used in connection with a thrashing machine has met a recognised want in some districts where large quantities of straw are used as chaff for the feeding of horses, cattle, or milch cows. As the machine we have alluded to is capable of cutting the straw as it is thrashed by an ordinary travelling machine it is very convenient, for it not only cuts the chaff but riddles out the cavings or imperfectly cut straw and all impurities, and delivers the chaff into sacks ready for removal. The chaff can also be cut of any required length for various purposes. The advantage of cutting straw into chaff at the time of thrashing is obvious, for if the corn is fit to thrash the straw must be also in condition for chaffing and storing for future use. This can be conveniently done upon most farms where there is a barn, for the chaff may be stored and kept in good condition, and used only as required. The best single-horse gear that we have seen is made by Reeves & Son, and is made expressly for working elevators, small chaff-cutters, food-preparing machines, &c., and is fitted with separate intermediate motion, which is enclosed so as to prevent anything being entangled in the gearing.

We must now refer to field rollers. It is noticeable that the heavy serrated roller or clod-crusher, made many years ago by Croskill & Co., is almost if not entirely gone out of use. The

reason for this is not far to seek. It consists chiefly of two important items. First, that smooth rollers are preferred, as they crush the clods into dust, whereas the serrated surface only breaks them into small angular pieces, yielding but little if any fine mould; the next is that practical farmers often do, and ought to, repudiate the policy or necessity of having any large clods to be broken, preferring that the labour required for reducing the soil into a fine state should be effected as fast as the land is ploughed, and reduced before it has time to become hardened. To prove the action of heavy smooth cylinder rollers, some fifty years ago we took a roller (which cost thirty-six guineas) into our farming stock, and it required four really good and powerful animals to work it on very rough land; but the action left the land perfectly fine both on the surface and under, for when two clods pressed against each other they were broken into dust, and we have often found that it would be impossible in some dry seasons to reduce really heavy clay land in a rough and cloddy state into tilth by any other means. Smooth rollers are most effective and valuable for park and pasture lands. Messrs. Woolnough & Co. and other makers have them up to the size of 36 inches in diameter of the cylinder, the draught of which requires four good horses.

We now desire to show the use and value of the ordinary two or three-ringed presser. The use of the three-ringed implement is the following of three ploughs; and as it is only animal labour to which we are referring, two full-sized horses, such as we have always recommended for farm work, if in good condition will be equal to the draught; but in the case of a two-ringed implement it will require two small horses or oxen, which shows the policy of using the presser of three rings. The home farmer will find this a most important implement, for all lea ground should be pressed at the time of ploughing in order to secure a firm and solid seed bed for either Wheat or Oats, to both of which crops it is necessary for their healthy growth. Speaking of Wheat, in the winter of 1878 and 1879 that which was sown after the presser was almost the only crop which maintained a full plant, for the seed being buried deeply it evaded the action of the severe frost. In the same manner Oats or drege, when sown after the presser, obtains a holding upon the firm subsoil at once, and thus to a great extent avoids injury by wireworm, grub, &c. We must also look to the finishing work of the tillage, for lea ground never works off fine and free from tufts of grass, roots, &c., unless the land has been pressed, nor is there any roller efficient in this work equal to the presser.

Ring rollers—such as those called the Cambridge, named after the original maker—are also capital implements as made by Messrs. Howard. These in ordinary work are better than smooth cylinder implements, because they can be used for nearly every purpose on the farm, grass land included; but they are especially necessary in the seeding of Clover and Grass seeds, for after the land is made fine on the surface, whether it is on Wheat land or spring corn, if the seeds are sown after the fluted roller the little firm channels made by the rings take the seeds so well that they become perfectly buried by one tine of the ordinary chain harrow, nor is there any other mode of seeding for Clovers and permanent pasture to our mind so perfect as that obtained by the use of the ring or fluted implement.

We have now to notice some useful articles required on the home farm, such as sheep troughs, cow cribs, cattle troughs, and corn bins, all of which are best when made of iron. It is quite common to use wooden articles instead of iron, but being constantly in use and exposed to all weather they soon wear out. The best galvanised iron sheep troughs for use in the open field are about 8 or 9 feet long, with two or four wheels, with a rod at the top to prevent the sheep treading in them; the lip or edge of these troughs are turned inwards, thus preventing the sheep from routing out the food. They are not covered except when required for the feeding of lambs, for when sheep are fed they should never have more food than they can eat before leaving the troughs; but not so with lambs, which should never see an empty trough, but always have food to eat, especially of corn and cake. In that case to prevent waste the troughs should be covered on the top and on one side. Iron cow cribs are not only convenient for feeding cattle and colts in the yards, but are very enduring; at the same time they are not easily turned over by the animals. Iron corn bins are to a certain extent a necessity, as are also the wrought iron cattle troughs, to supply water at all times in the stock yards.

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will be conducted according to the state of the weather. On some light gravel or sandy land Swedes will be sown after this time in order that they may be vigorous in growth during the autumn until frost comes, these late-sown roots being the only ones which are likely to stand during severe weather in the winter months. In preparing for Turnips after green crops, if the land is

foul with Couch, it is best not to clean-plough the land but rather plough, and then scarify across the rafter so that no Couch may be buried but kept well on the surface, to be dealt with by the self-lifting drag and roller. After the Couch has been cleared off the land may then be clean-ploughed rather shallow, in order that any remaining Couch may be worked out and removed before drilling the seed. Sow first the Scotch yellow hybrid variety, unless the crop is required for early feeding and early clearance, to be followed by Wheat, for then the Red Mammoth Turnip is the best variety; for when sown as a second crop they not only grow very fast but retain their quality and feeding value until a late period if required to stand the winter. If the green crops have been fed off by sheep 3 cwt. of superphosphate per acre, with 20 bushels of ashes, will be a sufficient dressing for drilling with the seed. If, however, the green crops have been removed for horses or cattle in the boxes, then  $1\frac{1}{2}$  to 2 cwt. per acre of Peruvian guano should be added to the before-named dressing. Horse-hoeing the Mangolds and Carrot crops will still be going on. We hear of considerable deficiencies in the plant of Mangold this year, but we cannot advise ploughing and resowing if Mangolds are required on the home farm, as they generally are; but we should prefer to plant Cabbage, Kohl Rabi, and Thousand-headed Kale. But the setting should be done at the back of the spade, as it moves the ground nicely round the plants, and also lets the plants down into the moist land—an important point, especially if the weather should be very hot and dry. In the sandy soils there will often be some Couch left, and which will show up at the time of horse-hoeing between the rows of Mangold, Turnips, and Cabbages. In this case we send women to take up the bunches of grass before the horse-hoes, and the Couch is eradicated for that season.

*Hand Labour.*—The men will be engaged in hand-hoeing and singling the root crops. In the latter work the women should assist, also in attending upon the hay when the weather is fine. After the ricks are made they should be tucked into shape and topped with straw, ready for thatching at the first opportunity if they are doing well and not likely to overheat. Hoeing Carrots must be continued between the lines. We prefer pulling them for the purpose of singling instead of using the hoe, because if the plants are set out singly as soon as the hoe can do it, then the crop is very liable to become a prey to the brown grub, for they grow slowly after being hoed out early. On the other hand, if they are allowed to become too large for the grub to eat before hoeing, a large bulk of food will be destroyed by the hoe to no purpose, whereas if they are hand-pulled the roots furnish a large amount of valuable food. We have obtained in this way from 7 tons to 10 tons per acre available as food for cattle, and if of the red intermediate sort there is a ready sale for them in towns as food for the people. The advantages, therefore, of pulling over hoeing are, first, you ensure a plant; then, if they are not pulled for thinning until the roots are the size of the finger or thumb, the ground is opened and loosened close to the standard plants, enabling them to swell very quickly. Again, the pulled roots are, if not sold, valuable food for all kinds of cattle, including horses and pigs. The work of planting Cabbage, Kohl Rabi, and Kale, should be continued, and upon land lately cleared of green fodder crops we prefer planting Cabbage plants to sowing with Turnips, for there is an amount of uncertainty connected with seeding which is not to be expected if planting any of the Cabbage tribe is properly done with the spade, and the land is made rich enough and kind enough by dung and good tillage to produce them in abundance, and especially we should provide abundance of plants for making out deficiencies and loss of plant amongst any of the root crops. We must not forget the value of Broccoli of the early sorts which come fit to sell from November to Christmas, as these pay remarkably well, and may be said to be a valuable accessory to our ordinary root crops, as they can be sold in towns and sent by rail to any part of the kingdom in the same manner that we get them packed and sent over from France and other parts abroad. They require, however, to be grown in a sheltered position and manured with guano, superphosphate, or nitrate of soda, and will pay well for it in some districts, the stumps being used as cattle food passed through the cutter and mixed with cake or bean meal. In this way we have fattened our bullocks on various occasions with as much profit as with Swedish Turnips prepared and given in the same manner.

*Live Stock.*—The cattle in the boxes are now getting forward for sale or for exhibition, and may have Clover, Saintfoin, Lucerne, Vetches, &c., with an ample allowance of cake and bean meal; and it will pay better on an average of seasons for cutting Clover twice or thrice than running the risk of making it into hay. We never make so good manure or make beef faster than when cattle are fed as above stated. Sheep should now have all been shorn of their wool, and all the lambs have been weaned also by this time. Weaning the lambs early tells in their favour as well as in advantage to the ewes, especially if the latter are intended for the butcher at the earliest period.

#### VARIETIES.

*STOCK-FEEDING.*—It is claimed by some feeders of stock that 100 lbs. of cornmeal and 100 lbs. of bran mixed will give a greater gain in flesh than 200 lbs. of meal. Meal and bran mixed is a better food than meal alone. Bran contains a larger per-centage of phos-

phoric acid, potash, and nitrogen than Indian meal, while the latter contains more oil, sugar, and starch than the former.

— **AMERICAN WHEAT.**—The "Prairie Farmer" states there was recently quite a flurry in Wheat in the Chicago market, the price going up 2 cents, closing at 1.10 dol. This is an advance of 5 cents in one week, and 8 cents since last winter. The causes are the over-estimate of last year's crop, a deficiency now in store there of about four million bushels as compared with last season, the large export demand, and the injury done the coming crop by the severe winter and the chinch bug. It is an open secret, too, that large quantities of the cash Wheat and options are controlled by speculators.

— **CRUSHED BONES AS POULTRY FOOD.**—Some persons are in the habit of burning the bones before giving them to poultry. It is true that after being burnt they are much easier broken up; but the raw bones contain a large amount of gelatine, which is a most excellent food for making hens lay, and gelatine also contains a large amount of nitrogen, which is driven into the atmosphere by the heat. When the bones are fed raw this nitrogen is retained, and having done duty as food for the poultry and constituting part of their systems, it is still capable of again doing duty as a fertiliser, but once becoming free nitrogen in the atmosphere it is not so easy a matter to combine it in such a manner that it shall be rendered available as plant food. In pounding raw bone it is not necessary to make it so fine as people suppose, for a hen will swallow a much larger piece than many would think possible, and when once in her crop it will be digested and properly economised. —(*American Cultivator.*)

— **THE BIRMINGHAM DAIRY SHOW.**—The Exhibition in all respects, with the exception of the attendance, proved an unqualified success. To what extent the receipts will fall short of the necessarily heavy expenditure has not yet been ascertained, and the Committee are consequently not aware to what extent the guarantee fund, which was previously subscribed, will have to be drawn upon. The financial result, though somewhat disappointing, is not surprising when the stagnation of trade and the severe depression under which the agricultural interest is labouring are considered. In a business point of view the exhibitors had no reason to complain. Such of the cattle as were for sale found purchasers at good prices, and the whole of the cheese and butter were readily disposed of.—(*Midland Counties Herald.*)

## POULTRY AND PIGEONS

### BANTAM CHICKENS.

WE have often written about the management of chickens in general, of our ways of tiding over the various crises in their existence, and especially of how to bring them to such a size as shall make them successful in the show pen and admirable on the table. Our subjects are usually suggested by what is going on in our own yards. The experiences and wants of one fancier are likely to be those of another, and so we generally follow up our routine by writing hints for fellow fanciers. The first object, as we have said, with most fanciers is to get size in their chickens; not so with all. Bantams, the beauty of which is their smallness, require a somewhat different treatment. They are seldom hatched in the early spring on account of their delicacy, and because Bantam hens are not usually early layers, and the present is a particularly good time for their appearance. We will, therefore, now give briefly a few results of our Bantam experience.

1. From the extraordinary activity of the young chicks it is sometimes said that they are very hardy. This is by no means the case speaking generally. Game Bantams, it is true, if not in-bred are hardy enough, but almost all strains of Bantams have been much in-bred to keep them small; they also feather all over with extraordinary rapidity. The result is, that the first month of their existence is a season of delicacy, and care they must have. There is with them, as with young Turkeys, a crisis, and when this is once passed, they rapidly harden. They are extremely susceptible of damp; their coops must therefore be thoroughly watertight with projecting weather-boards in front to keep out driving rains. We prefer two-boarded floors with removeable drawers

for them, unless the coop can be placed altogether in a dry shed; this, perhaps, is the best plan. A damp floor soon brings on diarrhoea in the smaller chickens; they refuse food and pine away.

2. The system of feeding young Bantams differs much from that suitable for larger breeds. Smallness being a desideratum, oatmeal, milk, and such bone-making diet must be avoided. A mistake, however, is often made in starving Bantams; this they will not bear in their early days, the rapid growth of their feathers requires constant nourishment. When, however, they are half grown this must cease; henceforth no fowls require so little food. Multitudes of adult Bantams are killed by overfeeding. For the first fortnight bread crumbs and chopped hard-boiled eggs will be found good, and plenty of boiled rice. At this time of year all chickens are the better for plenty of rice, and specially Bantams. Six meals a day not too many for them. Groats will succeed the egg. Oats in this hard form does not encourage quick growth so much as in the form of meal.

3. In the case of large fowls our object is to keep them chicken-like as long as possible, in that of Bantams to bring them to the earliest possible maturity. From the day of their hatching, therefore, till they are full grown they may have stimulants. For the first few weeks a little finely minced meat daily helps them on; no chickens show such an extraordinary craving for it. We have often seen little Bantams nearly tearing each other to pieces over a worm or bit of meat. Ants' eggs, too, are excellent where they can be got, and as the little things approach maturity some of the spiced foods, which we condemn for the large breeds, will come in usefully. It must not be forgotten then, though it is generally useless to take extra trouble over a specially backward or delicate chick in the case of the larger breeds—in fact, we generally advise the killing of all such—the little Bantam which continues a dwarf but yet exists, providing it has no real and infectious disease, may prove a veritable treasure from its diminutive size. As we have said of sickly Turkey poults, that as long as there is life there is hope, and that special attention will often save one apparently far gone, so it is with Bantams.

One more point is there of difference in Bantam régime. No trouble need be taken about separating the sexes as they grow up. The adult plumage, especially of the cocks, develops all the more rapidly when all run together. We have before now written of the difference between the breeds of Bantams which are of modern production and the really old breeds. In the case of the latter there is really little difficulty in keeping them down to small size; the former, having been reduced from large breeds, are ever apt to return to their natural size. It is to these that special care has to be given in their infancy, and we hope that our experience may be of some use in helping others to avoid some of the failures which we have from time to time suffered from.—C.

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 500.)

#### MAKING NEW VARIETIES.

OUR American friends have more experience in the manufacture of new varieties than fanciers on this side of the Atlantic can lay claim to. Their efforts in this direction have been by no means wanting in success—witness the several varieties of Leghorns, the now-popular Plymouth Rocks, and the last new addition to the American standard the Java fowl. It is true that occasionally an English fancier makes an effort to strike out a new line; but, whatever may have been the case some twenty years ago, when the fancy was comparatively in its infancy here, there is no doubt that now-a-days the attempts made to bring forward new breeds of home manufacture do not meet with much encouragement. The outcry raised against the so-called Eymore Blacks exhibited at a recent Birmingham show is a case in point.

Notwithstanding this prejudice against manufactured breeds there is, we think, plenty of room for new varieties, especially from the utilitarian point of view. The breed has yet to be found which shall combine first-rate table qualities with an abundant supply of good-sized eggs and perfect adaptability to our English climate. The Houdan is perhaps nearest to the desired standard; but there are Houdans and Houdans, some being good in all the points mentioned, while others are just the opposite. The Dorking is essentially the table fowl of England; but then, except in rare cases, the supply of eggs is not abundant and the chickens are often difficult to rear. The Langshan claims to have hit the mark, but its feathered legs and strong infusion of Black Cochins blood are against it. The Spanish sub-varieties are all very well as layers, but have no claims to be considered first-rate table fowls, and the small size of the eggs of the Leghorn is an objection with many people. We might go in like manner through all

the well-known breeds, and point out the respects in which each falls short of the requirements of the poultry farmer; and, with the exception of some few enthusiasts who would uphold their own particular breed as being perfect against all comers, we think most practical men would agree with us that there is plenty of room for improvement.

From the point of view of the fancier there is also plenty of room for new varieties, provided they be distinct and sufficiently established not to betray the original elements from which they have been manufactured. It is probably on account of the premature way in which the results of English attempts to form new breeds have been brought forward that they have failed to attain anything like the success of imported specimens of manufacture. We have also a national prejudice in favour of being imposed upon; and just as we accept American bacon more readily when it is labelled "Best Limerick" and sold at a high figure than when it is truly described and priced accordingly, so we much prefer to be told that our new varieties of poultry are descended from birds imported from some unknown region rather than learn the truth as to the elements from which they were formed.

New varieties are manufactured in several ways. One of these, and that most largely resorted to, is to cross two or more known breeds until something like the type desired has been produced, and then by in-breeding and artificial selection endeavour to attain and perpetuate that type. This is work which requires much patience, as the tendency to throw back always comes largely into play in such cases. It is a good plan in making such experiments to start with two similar distantly related pairs of birds, and carry on the process of breeding from the progeny of each pair separately for some time, afterwards crossing them with each other when fresh blood is necessary. The chances of throwing back when fresh blood is introduced are thus much diminished, the fresh blood being of a similar type and produced in a similar way to the strain into which it is introduced.

It is by some such method as this that good laying and table qualities might be combined in one variety. At present the poultry farmer generally looks to first crosses for such results, but this method necessitates the keeping-up of a breeding stock of each of the varieties used for the production of the cross or the purchase of fresh birds each year, and has the additional disadvantage of being somewhat uncertain in its results. Precisely similar crosses do not always succeed equally well or produce similar results, while a strain bred for certain qualities can be relied on to reproduce them with reasonable certainty.

Another method adopted in the production of new varieties is to take advantage of some sport from a known variety, and by in-breeding to it and selection perpetuate the accidental type. Nature commits vagaries in the poultry yard and Pigeon loft just as in the garden, and such of these sports as are of beauty are worth the trouble of an attempt to perpetuate them. Such has been the origin of several of our white varieties which have been thrown from black parents, and cuckoo and slate-coloured birds have also in several cases originated in sports from black or white, though more frequently from crosses between black and white.

One more source of new varieties deserves a passing mention. When, amongst the miscellaneous and generally mongrel contents of a farmyard some type worthy of perpetuation seems to appear with more than ordinary frequency, an attempt may be made to fix it in the way already described. This is generally the most difficult case to deal with, as the diversity of the sources from which the points of the birds are derived renders it almost impossible to get any settled type reproduced.

No variety can be said to be established until the points for which it is bred are so fixed as to be reproduced with a fair amount of certainty. The poultry farmer must take care that he does not allow the pursuit of fancy points to lead him away from the objects he has mainly in view. For him these are of minor importance. Hardiness, early maturity, plenty of meat of good quality, with a small proportion of bones and offal and first-rate laying properties, are the points he should regard in his efforts at improvement. A variety which would reproduce these points with certainty, though hardly a new variety from a fancier's point of view, would be worthy all the trouble that could be expended upon its manufacture, and would amply repay its producer.

(To be continued.)

### CROSS-BRED FOWLS AT THE BIRMINGHAM DAIRY SHOW.

WE looked forward with some interest to seeing the classes for cross-bred poultry at Birmingham. We have written on the subject of crosses, and believe that much might be done by some real study

of their results to improve table poultry. Our expectations were hardly realised at Bingley Hall. The first class we came to was for trios of adult cross-bred fowls. There were four prizes, of £5 in all, and only six pens were entered. The pen which struck us as containing much the best fowls for the purpose was Lady Dartmouth's (No. 515), from a Cuckoo Dorking cock and Silver Poland hen. We have before advocated a Dorking-Poland cross, and much fancied these. They are small-boned, plump-breasted birds, and pretty too; Cuckoo in plumage with moderate crests. A class for three chickens of like kind and with the same valuable prizes followed, but there were only five entries. First went to Mr. Butler Smith, not correctly we thought, for his birds bore no trace of being cross-bred, but were apparently bad-bred Dark Dorkings; big enough it is true.

The open classes for the heaviest dozen of eggs were wonderfully filled with eggs of marvellous size. Though there were only two prizes in each class no less than forty-two entries of hens' eggs and twelve of Ducks' were made. Many exhibitors had sent double-yolked eggs, but the Judges very properly tried and left out any collections showing signs of being such. First went to the produce of Andalusians, and second to that of a Cochins and Dorking cross. In the class for Ducks' eggs Aylesburys carried off both the prizes. In the classes confined to Warwickshire tenant farmers and cottagers almost all the prizes, both for cross-bred fowls and for eggs, were carried off by Mr. Frederick Lythall of Offchurch near Leamington. Dressed poultry looked better than they usually do at such exhibitions. For pairs of chickens, judged irrespectively of weight, we were surprised to see first given to Brahmas, in preference to two very plump tempting-looking Dorkings from Mr. T. C. Burnell, priced at the modest sum of 4s., and of course sold. Two capons alone were entered for two prizes, of £1 and 10s. They were grand ones, however, sent by the Hon. Mrs. Colville.

Surely those interested in table poultry will remember against another year the great and liberal encouragement given at this Show to its production. We can only hope that the meagreness of the entries will not cause the prizes to be cut down at the show which we hope will take place next year.—C.

### OUR LETTER BOX.

**Roup (G. P.).**—We hardly think your birds have anything more than colds. Take care that they are comfortably housed and have a well-drained run. Do not allow them to be exposed to rain or wet under foot. Put a few drops of sulphuric acid and a few of nitric acid in the drinking water, adding a little sugar to take off the very bitter taste. Give bread and ale or some other stimulant. Should the symptoms increase, wash the nostrils, eyes, &c., with Labarraque's solution of chlorinated soda diluted with twice the quantity of water, and give one dose of castor oil followed by a copaiba capsule twice daily. The birds affected must be separated from the others or the disease will run through the yard. Use some disinfectant in the yards where the roup birds have been. Give your chickens sound meal, and feed regularly, leaving no food lying about. Pay especial regard to cleanliness.

**Crossing Rabbits (J. B.).**—You may reasonably expect to have at least some good animals from the cross you propose. We are not able to state where you can obtain a cap for training refractory Rabbit ears in the right direction; perhaps some of our readers can supply the information, or how such a cap can be made.

**Cutting Hay (T. M.).**—The clause in the agreement, "cut once in hay not allowed to seed," is a reasonable one, and fairly interpreted means that the hay should be cut when the majority of the grasses are commencing to flower, not waiting until they have flowered. The process of ripening the seed of grass or any other crops seriously exhausts the land and weakens the plants, and consequently to defer the cutting until seeds have ripened is disadvantageous both to the landlord and tenant when the produce is grown for fodder. The hay, further, is much more nutritious when the grass is cut just as flowering commences than when it is left until the seed ripens.

### REMARKS.

12th.—Fine, warm, pleasant day, rather overcast at times.  
13th.—Fine, bright, and warm, overcast at intervals.  
14th.—Cloudy and close, latter part of the day finer.  
15th.—Morning overcast; afternoon and evening fine.  
16th.—Warm, overcast, with sunshine at intervals; very slight rain in evening.  
17th.—Close and oppressive; some heavy rain in evening.  
18th.—Fine, but overcast and gloomy; a shower at 11 P.M., but the amount not measurable.

A rather dull week of nearly the average temperature.—G. J. SYMONS.

30th	TH	Richmond, Farnham, and Canterbury Shows.
1st	F	Strawberry and Cherry Show at the Alexandra Palace.
2nd	S	National Rose Society's Exhibition, Crystal Palace.
3rd	SUN	3RD SUNDAY AFTER TRINITY.
4th	M	Maidstone Rose Show.
5th	TU	Reigate, Harrow, Rochester, and Stourbridge Shows.
6th	W	Royal Botanic Summer Show. Cardiff, Norwood, & Wimbledon [Shows.]

### PREPARING FOR WINTER.

THOSE who are not deeply versed in the mysteries of gardening may perhaps think remarks under this heading somewhat premature, the more so as we can scarcely be said to have entered the summer season. But gardeners are required to look ahead, and long before one season is past they must be preparing for the corresponding period in the year following. Preparing for winter is no small matter; on the contrary, it entails a great amount of forethought and labour, which must be well and carefully performed. Procrastination with gardeners very frequently means either a partial or complete failure, and at no time is this more evident than when preparing for the winter. To attempt to treat upon all that requires preparation in one or two papers scarcely admits of justice being done to the theme; at the same time I shall endeavour to write as briefly as possible, commencing with some important crops requiring immediate attention.

#### STRAWBERRIES.

Probably no forced crops, provided they are good, give more pleasure to all concerned than Strawberries. Much trouble is certainly entailed in their culture, but if not forced very early no one can say they are unprofitable. Now is the time to layer the runners, and which method is most economical, and which are the best varieties for forcing, are the questions to be considered. The selection of varieties ought to depend entirely upon circumstances. Black Prince is suitable for very early forcing in 5-inch pots, but the fruits are too small to please many. Vicomtesse Hericart de Thury forces well and crops heavily; the fruits, however, are not large nor early in the season of the best quality. Keens' Seedling is still one of the best early varieties, and La Grosse Sucrée forms an admirable succession, though, unfortunately, the fruit travels badly. Sir Joseph Paxton forces well, and the fruit is large and firm. President also crops heavily, and the fruits are also large and handsome. British Queen and Dr. Hogg are equally good for late crops, the quality of both being very fine. I am required to have fine fruit ripe and of good flavour by the first week in April, and it has to be sent to the town house. My selection is Keens' Seedling, Vicomtesse Hericart de Thury, La Grosse Sucrée, and Sir Joseph Paxton. The three former will be fruited in 6-inch pots to the extent of two-thirds of the stock, the remainder being Sir Joseph Paxton in 8-inch pots, and these will continue the supply till the earliest plants on south borders are ripening fruit.

Opinions vary as to which is the best method of securing strong well-rooted plants for forcing, that most in vogue being

to layer into 3-inch pots and to shift into 6-inch pots. Several practical men I am acquainted with prefer layering direct into fruiting pots, and the results certainly appear to justify the practice. Strawberries must be potted firmly, and the young hands, and some old ones too I find, are apt to be careless in this respect, and that is a reason for advocating layering direct into fruiting pots, the ramming being more easily and therefore more surely performed prior to the runners being pegged down. My only objection to the practice is the fact of the necessarily heavy trampling appearing to injuriously affect the beds, and for my part I never experienced much difficulty in well filling the pots with roots. All my runners will be secured from old forced plants now in the open ground, and a number of small plants recently turned out of small pots and planted between some Gooseberry bushes and Box edgings. Early strong runners are thus obtained. Those intended for 8-inch pots and for planting-out will be layered into 3-inch pots, and the others direct into 6-inch pots. The soil employed will consist of strong and rather clayey loam, to every four barrowloads of which will be added one of sifted decomposed manure, and this mixture will in every case be made as firm as possible. Clean pots are needed, and in the case of the large sizes good drainage is essential; and I think it advisable to place a thin layer of moss over the potsherds, sprinkling a little soot on this, which will both assist the plants and tend to exclude worms. The young layered plants are separated from the old stools as soon as established, and where it is required they are transferred into the large pots before becoming much rootbound. The plants to be arranged in beds on ashes, and in a sunny open spot, avoiding crowding, and at no time from the date of layering to finishing the crop of fruit must the soil be allowed to become very dry. Strong well-established plants do not require to be stored in frames to protect them from frost, but it is advisable to plunge in ashes and other material to preserve the pots from cracking. We have a rough frame for storing away the plants intended for early work, and this frame is afterwards utilised for dwarf early Peas.

#### BROCCOLI AND WINTER GREENS.

In spite of the two disastrous winters, it is very probable that these crops will be grown more extensively than ever. The late dearth among these green crops has decided many to make more strenuous exertions to maintain a supply. Never, perhaps, was a worse start made than this season, as it seemed impossible to secure enough plants to place out. The first batches in the open were cleared off as they showed above ground, and even strong Cauliflower plants could make no headway against the ravages of the small beetle that attacks them. The next sowing nearly shared the same fate, and eventually the remainder of the seed had to be sown in hand lights. The plants thus obtained are now pricked out and are growing satisfactorily.

It is a very common practice to sow the seed of the Brassicas on sheltered borders, often in small beds, where the plants remain in a crowded state till the ground may be cleared for their reception. This is a decidedly bad commencement: it is better by far to prick out the young seedlings when in rough leaf, choosing showery weather for the operation. Plants thus treated will not only be sturdy, but can easily be lifted with a good ball of soil attached, which is of importance in late planting. The unusually vigorous growth of the Potato

haulm last season, unless the rows were very widely disposed, completely overran the winter vegetables planted between them, and it is not unlikely the same thing will occur this season. For this reason I advise those who wisely have taken the precaution of planting good breadths of early and second early Potatoes to first lift these as soon as matured (the haulm need not be ripe nor the skin of the tubers set), and, clearing off rubbish and heavily trampling the ground, to at once fill up with the winter vegetables. Supposing the Potatoes to be lifted during hot dry weather, the drills for the crops under notice may be drawn about 3 feet apart, and be filled with water a few hours prior to planting. All strong-growing varieties may be planted 2 feet or 30 inches asunder in the rows, and should be planted with a trowel and have the soil firmly rammed about the roots. Two or more waterings will perhaps be required before the plants are established, afterwards the soil should be drawn up to the plants to enclose moisture and also to steady them.

Broccoli will not only grow in solid undug ground, but the growth there is of such a description as to best withstand our winters. A freshly cleared Strawberry bed is especially suitable, and the drills may either be cut out with a heavy hoe and soaked with water, or the holes for the plants may be made with a crowbar. Ground recently occupied with Peas and Beans may be similarly treated, but if very poor the drills should be soaked with liquid manure. In these cases there is no necessity to bury the stems as a protection from frost. In our case a large breadth of ground outside the walls, which is unsuitable for Potatoes, will be filled with Broccoli, and the whole of these lifted with balls of earth attached, placed on handbarrows, carried to the highest part of the garden inside the walls and laid in. The heads will face to the north and will be packed rather closely. The whole of the stems will be covered with earth, a liberal quantity of manure being worked in with the roots. Early in October will be the time chosen for the operation, which will allow the Broccoli good time to recover themselves. By this method I have every confidence in being able to secure a large number of fair heads, towards the size of which the manure will materially contribute. A good batch of Snow's Winter White and Veitch's Autumn Protecting will be lifted and stored in rough pits, others of the same variety on solid ground will be left to take their chance in the hope of getting early supplies. Last season a batch of late-planted Veitch's Autumn Cauliflower on a sheltered border yielded a number of very acceptable heads till late in December. I shall repeat the experiment.

#### BRUSSELS SPROUTS.

These to be profitable ought now to be growing freely, but in some seasons late-planted breadths prove remunerative. These are best grown on rich solid ground, or rather on newly-manured fresh soil. Where the plants are much drawn up in the seed beds, rather than dibble them in deeply I advise laying them in sloping trenches, shaking some manure about the roots, and covering the stems with the soil from the next trench, treading it firmly about them. The plants soon become upright and may do well. Kales are very hardy and should be grown extensively, and Savoy's should be planted in good quantities, the small kinds being especially suitable for narrow borders.

#### COLEWORTS.

If these are not already sown no further time should be lost, as they will be found very serviceable and should be grown in quantity. The Rosette Colewort is the most hardy and reliable, and large breadths of it cannot fail to prove useful. The plants may be dibbled in about 15 inches apart each way, and will do well in succession to autumn-sown Onions. They can also be planted after widely-planted Potatoes, and between the rows of winter vegetables.—W. IGGULDEN, *Marston*.

(To be continued.)

A PLAGUE OF BLACKBEETLES.—Paragraphs with the above heading have appeared in various newspapers, referring to the abundance of the blackbeetle or cockroach (*Blatta orientalis*) in London this summer. A similar circumstance I have noticed in a country town, where this insect has been found about houses in

which it had not been seen for years. It is necessary that gardeners should remember (as I pointed out in this Journal some seven years since), that this species is fond of making excursions from human habitations to gardens and greenhouses that may be adjacent, and will do mischief at night to plants or sometimes to fruit. Phosphorus paste, especially in the form of "Chase's beetle poison," which requires no mixing, is efficacious in killing some, and (seemingly) in scaring away others, or hundreds may be caught in traps by a little bear or syrup. The rinds of the Cucumber have been said to be destructive to them, but I have not found such a result from placing these in their haunts.—J. R. S. C.

#### ABUTILONS.

FEW plants can be more strongly recommended for blooming in our greenhouses and conservatories throughout the spring, summer, autumn, and winter than these. They are almost the only plants from which flowers may be cut every day in the year; yet Abutilons have scant attention by writers in the gardening press. But silence in this respect must not be regarded as disparaging to the plants, as the improved varieties of Abutilons are not generally known. The best known sorts are *A. Boule de Neige* and *A. rosea*, white and pale rose; and although the white variety is good, the other is inferior in size of flower. When we come to colours there are abundance of fine flowers to choose from in purples, pinks, yellows, lilacs, and intermediate shades. I have no list of names to submit, as all our best varieties have been had from seed, and I cannot do better than advise those beginning the culture of Abutilons to obtain a packet of mixed seed. From this many plants may be obtained, and in all probability excellent varieties.

An amateur cultivator in my neighbourhood has a great fancy for Abutilons, and nearly every corner of his small glass structures are occupied with plants. All the best of his flowers have been raised from seed obtained from a firm that frequently advertises in this Journal, and the best of ours have been had from the same source. Many of these seedlings surpass any named varieties I have seen in habit of growth, profuseness of blooming, and richness of colours.

Those who have no Abutilons would find it an advantage to procure a few plants now, and at the same time sow a packet of seed. The small plants would supply a luxuriant crop of flowers in the autumn, and the seedlings would bloom by the new year and onwards. Then there would be no break in the supply, because as growth proceeds flowers are emitted from every joint, and often in clusters or handfuls.

The culture of the plants is simple. Cuttings root freely with a very slight bottom heat in winter and early spring, and in summer they do not need this, as a close frame is all that is wanted for propagation. They may be rooted singly in small pots, or numbers together in 5 or 6-inch pots; and seed sown at the same time and in the same frame will furnish plants which, when a few inches high, will come under the same treatment as newly rooted cuttings. As soon as a few roots have been formed the plants must be potted in a mixture of loam, leaf soil, and sand; but at subsequent pottings more loam must be used and decayed manure substituted for leaf soil. The plants may be flowered in 6-inch pots if required; but if fine specimens are wanted and a large supply of flowers, 8-inch or 10-inch pots may be employed. Good drainage at all times is essential to success.

Immediately after each potting it will be necessary to keep the plants in a close atmosphere for a few days, but when growing a cold frame or cool house is their proper place in summer and autumn, and a slightly warmer place suits them well in winter. Unlike some of our best and most showy flowering plants they are not liable to become infested with insects, and in this respect alone they save amateurs much expense and trouble. The flowers, too, are very hardy, and not in any danger of damping off in cold moist weather. Our plants do well in frames and cold houses from March until October, when they have the assistance of a little warmth to keep them growing. Some of them are planted out and trained in odd corners or up pillars. These are most useful for affording flowers for cutting, as they grow and flower more freely than those in pots; but the latter are the most useful for various purposes of decoration, and we therefore find it profitable to grow them in both ways.

In training, the wall and pillar plants are allowed to grow unchecked, but in pots they are restricted and grown into bushy specimens. As it is on the points of the shoots that the flowers are produced, these may be allowed sometimes to grow out of proportion to the symmetry of the plant, as no one likes to take the points out of plants when they are full of flower buds; but the plants at certain seasons may be cut closely down to the soil, and

they will soon become more compact, as they bear cutting and training to almost any extent.

Plants which may have been blooming throughout the summer will have their pots well filled with roots in autumn, and do not make such strong growth in a close warm place in winter as late-rooted plants do. During winter they open quantities of their useful bell-shaped flowers in a greenhouse temperature, but a little additional heat is sometimes of advantage in maintaining a full supply.—M. M.

#### HORTICULTURAL KNOWLEDGE.

"INQUIRER" appears to have a vivid recollection of his youthful days of high and rigid temperatures. He has known "the men" blow the glass up, and thus have the heat at the regulation point for the foreman. He does not say whether he was one of the "men" or the foreman, but that is of little consequence. Working under the tyranny of high and stipulated temperatures, from which the deviation of two degrees often or always led to a "scene," I have in the interests of peace and morality been guilty not only of thus momentarily raising the temperature, but have syringed the hot-water pipes for a quarter of an hour, and so gained two or three degrees to preserve my credit as a fireman; but I am afraid the after-condensation was not beneficial to the winter Cucumbers and early Vines. I have also found it necessary to throw open front and back ventilators on a frosty night to bring down the temperature from 76° to 74° at a critical moment. If there are any gardeners left who determine that the temperature shall be kept "to a degree," they may as well know that if they are hard taskmasters they are similarly imposed upon, for they expect an impossibility, and the men do their best to meet the extraordinary demands. But I did not prove an "unthinking pupil." I thought then the principle of high night temperatures and an unflinching adherence to stipulated figures was a fallacy, and determined to test the point on the first opportunity. I have been testing it for twenty years and find I can produce as good if not better Grapes than under the nocturnal driving system, while it is a fact that I have saved coals to the extent of more than half my wages. Having had experience of both the systems referred to, I find that very fine Grapes can be grown under the former for a few years, but the Vines then need renovating, but under a more natural, and, I think, rational mode of culture, they continue healthy and fruitful for an indefinite time. I have had as fine sets of Black Hamburgs at a minimum of 50°, and Muscats ranging between 55° and 60°, as I ever saw when the night temperatures were on an average 10° higher. Yet I cannot forget that if now I am successful, then I was—A CULPRIT.

#### REVIEW OF BOOK.

*A Manual of the Coniferæ, with Numerous Woodcuts and Illustrations.* London: James Veitch & Sons.

THE aim of this work is to treat of the Coniferous family in a manner which shall be intelligible to the commonest understanding, so that those who have not had what is called a scientific education will in it possess a text book freed from the ordinary conventional technicalities which so much bewilder the uninitiated. The authors have succeeded in their object, and we have before us a work of 342 pages, which treats of the subject clearly and intelligibly.

The work is divided into three parts. Part I commences with a "General Review of Coniferous Plants," and treats of the structure of the wood, the organs of vegetation and fructification, the secretions, economic properties, the diseases and accidents to which the trees are liable, their geographical distribution, and their scientific arrangement and nomenclature as given by the most eminent botanists. Several pages are also devoted to the literature of the Coniferæ, which affords evidence that much pains and research have been exercised in rendering this section of the work both interesting and instructive.

The second part opens with a synopsis of the genera, species, and varieties suitable for cultivation in Great Britain, followed by copious descriptive, historical, and cultural notes of the different species, arranged in the sections under which they are grouped. For instance, the Abies are divided into three sections. I. Piceæ, the Spruce Firs; II. Sapini, the Silver Firs; III. Tsugæ, the Hemlock Firs. The notes on the species in each genus are preceded by tables in five columns, the first column containing the scientific name, the second the synonymes, the third the popular name, the fourth the habitat, and the fifth average height of each species. Then follows in alphabetical order the notes referred to—some brief, some copious, as the subject demands. In the treatment of the species and varieties there appears to have been

no over-writing on the one hand, nor hesitation to incorporate matter on the other when anything interesting could be advanced relative to the origin, discovery, or peculiarity of the different forms; also, as intimately connected with the subject, biographical notes are incorporated of such collectors as Douglas, Hartweg, Menzies, Jeffreys, Lambert, and Lobb. The references to the lives and work of some of the more famed collectors are copious and full of interest. We observe, however, an error in indexing, for the note in reference to Lambert is on page 180, not on 188 as stated. The part of the work under notice is by far the largest, embracing 260 pages, and the most important; but whether the plan of including the Silver Firs under the head Abies instead of Picea will meet with general acceptance is an open question. Piceas pectinata, nobilis, Pinsapo, and others will probably remain Piceas in the view of the majority of British cultivators, and there is at least equal justification for this as for the retention of the name Wellingtonia, instead of the more strictly accurate name of Sequoia gigantea.

The question of generic classification as well as specific nomenclature in the Coniferæ is admittedly a difficult one. The diver-

Fig. 117.—Cone of *Abies bracteata*.

gence of opinion among authorities is strikingly manifest, and stands out boldly even throughout the work under notice. In respect of some of the species endeavour has been made to amend the nomenclature, as in the case of *Abies lasiocarpa*, with its half dozen synonymes, and the true name of which is determined on page 94 of the book as being *A. concolor*; but better reasons are given for the substitution of *Sequoia* for *Wellingtonia*, yet English custom has proved stronger than international science in this case, and the popular name is retained.

The work is copiously illustrated. There are many excellent engravings of notable specimens, cones and sprays. The first specimen represented is of *Abies orientalis*, 53 feet high, at Highnam Court. Then follows *Abies bracteata*, 29 feet high, as growing at Tortworth Court. Lobb said of this species that the "cones are quite as singular as the growth of the tree is beautiful." We submit one in proof of this, and also as representing the character of the engravings of the work under notice. *A. concolor* or *lasiocarpa*, 46 feet high, is shown from a fine specimen in Mr. Gambier Parry's collection; but a more perfect and handsome example about the same height may be seen at Orton Hall, Peterborough (Dowager Marchioness of Huntly's), and near it, also fine, *A. Lowiana* or *Parsonii*, the two trees being quite dissimilar.

*Abies nobilis* at Highnam Court, 60 feet high, is also shown, with a grand cone of this beautiful Fir. *Cedrus Deodara* at Dropmore, 64 feet high, and a varietal form at Tortworth, 41 feet high, are figured. The Dropmore example is probably one of the specimens that were raised from seed sent there by the introducer, the Hon. W. Leslie Melville, about 1831. A letter is before us from the brother of this gentleman, the Hon. Alexander Leslie Melville, of Branston Hall, Lincoln, under date June 11th, 1881, which states that "The first Deodar seed that vegetated in England was brought by my brother in his waistcoat pocket. The plants were raised at Dropmore. In 1854 my brother sent an artist to make a drawing of them, which I now possess. The trees seem to thrive well about London and to the south of it. A severe winter has killed most of them in the north, where the frost has been intense. In 1859-60 they were killed at Woodhall Park, Herts. Some later plants than those at Dropmore are thriving well at Melville House, Fife, N.B." These trees, which we have seen, are, however, old and divested of their lower branches. Much interesting matter is given relative to this beautiful Cedar, but its liability to be destroyed during severe winters, as stated by Mr. Melville, is omitted, doubtless by inadvertence; for it is one of the merits of the volume that the drawbacks of many of the species are described as freely as their merits are extolled. This is plainly manifest in the notes referring to the Mexican Pines that were introduced by Hartweg, for of one of the commonest of them—*P. Montezumae*—it is stated "it is not hardy;" but in the collection above referred to near Peterborough a handsome specimen 25 feet high has passed the late severe winters, when the frost approached zero, without having received the slightest injury. Its fine varietal form, *P. macrophylla*, is very much larger in the same collection. This, too, has passed scatheless, while the *Wellingtonias* around it were much browned and *Abies bracteata* injured. The leaves of *A. microphylla* are fully a foot long and droop gracefully, those of the species assuming an incurved upward position, and are stouter in texture and shorter. This evidence as to the hardiness of these imposing Mexican Pines will not be without interest.

The chapter on the *Wellingtonia* is elaborate, but little or nothing is stated as to the uses of the wood, a matter of some importance, seeing that thousands of specimens in this country have attained the dimensions of timber trees. On the subject of utility we are able to state that from a collection of upwards of three hundred specimens, some of them between 50 and 60 feet high, large trees have been felled, the trunks exceeding 4 feet in diameter, the wood having been applied to various purposes, and has proved practically speaking worthless.

The chapter on *Araucarias* includes an illustration of the splendid Dropmore specimen, the present height of which is 61 feet, and the tree is perfectly furnished. In the deciduous Cypress section is an illustration of the remarkable old specimen of *Taxodium distichum* at Syon House, 90 feet high, with "knees" or protuberances from the roots. It is stated that "no cause has been assigned for the existence of these 'knees,' but they are made use of by the Negroes of the Southern States for bee hives." An example of *Cryptomeria elegans*, 20 feet high, at Linton Park, and one of *C. Lobbi*, 46 feet high, at Dropmore, are represented. There is also shown a group of Japanese Conifers (*Retinosporas*) at Linton Park, also a fine example of *Thuia gigantea* in the same collection 50 feet high; and a well-finished example of the beautiful *Thuopsis dolabrata* in Lord Brownlow's collection at Ashridge. The height of this is not named—a small but rather important omission, as, judged by the relative height of the preceding figure, the specimen in question would be about 40 feet high, which cannot be the case. The chapter on the Incense Cedars (*Libocedrus*) is necessarily short, those on the Junipers and *Taxads* being very complete. In the section devoted to the Fetid Yews it is stated that "Torreyas do not thrive well in Great Britain, but in their scientific aspect they possess a deep interest." It is unfortunate that they do not usually succeed in English gardens, as a fruiting specimen of the Californian Nutmeg (*T. myristica*), from which seedlings have been raised, is a beautiful ornament in the garden at Northamptonshire, which has been previously referred to.

The third part of the work treats on the various purposes for which the Coniferae are planted, and imparts information of great practical value. Selected lists are given of kinds suitable for planting in parks, pleasure grounds, avenues, also for evergreen hedges, for belts and screens, the conservatory and winter garden, as memorial trees, and for cemeteries and burial grounds; the concluding chapters being devoted to Coniferous trees valuable for their timber, and a reference to the collection of cones in the museum in the Chelsea nursery, which is open to the inspection of visitors.

As will be gathered from this notice the work is a comprehensive one—essentially practical to be of substantial utility, and sufficiently technical to be educationally instructive. Considering its magnitude and complexity, the subject has been treated in a manner for which Messrs. Veitch deserve warm commendation. The volume is excellently printed, and should be possessed by all who are interested in the Coniferae, on which it will rank as a standard work, and will no doubt be included in public as well as private libraries. For the next edition, however, we would suggest a much more copious index, which would greatly enhance the value of the book as a work of reference.

#### TUBEROUS BEGONIAS AT FOREST HILL.

MESSRS. JOHN LAING & Co. have justly earned an almost world-wide fame for their Tuberous Begonias, as the experience and careful attention brought to bear upon the crossing of these popular plants have resulted in the production of many varieties of unrivalled beauty; indeed, a very large proportion of the best forms grown in English gardens at the present time have either being raised at the Forest Hill nurseries or sent into commerce from that emporium. Consequently a visit to the establishment is invested with more than ordinary interest to all lovers of this attractive section of the genus *Begonia*, and to obtain an adequate idea of the range of variation in the size, form, and colours distinguishing the flowers, together with a conception of the enormous demand now existing for such plants, a better time than the past or present week could scarcely be chosen for the purpose. Several large glass structures are devoted to the plants, but the majority of the large specimens representing the best single varieties are arranged in a span-roof house nearly 100 feet long. The effect produced by the abundant brilliant scarlet, soft rose, delicate yellow, or pure white flowers, is not only most striking, but is probably unequalled as regards the general excellence of the varieties and plants. Annually a great number of seedlings are raised by carefully crossing all the finest forms, in every case with some distinct object in view, to improve the form or size, or obtain a novel shade of colour. Amongst the diversities thus secured there are necessarily many that surpass in some point varieties previously raised, and from these the most distinctly marked are selected for naming and distributing. That a most rigid exclusion is practised may be gathered from the fact that many thousands of seedlings are raised to produce comparatively few varieties considered sufficiently meritorious to be recommended to the public, and in one portion of the nursery nearly ten thousand seedlings are planted out for trial during the present season.

To enumerate all the really handsome varieties would require considerable space, and would indeed be unnecessary; but some of the novelties and a few of the most remarkable of the older forms may be advantageously mentioned to indicate the predominating characters of the principal types, commencing with the single-flowered section. Perhaps the finest variety that has yet been seen in respect to size, regularity of form, and brilliancy of colour is a seedling recently raised, and which on the day of our visit was entered in the list of named novelties as Consul Darlington. The flowers in several instances were  $4\frac{1}{2}$  by 5 inches in diameter, each of the larger pair of petals being neatly rounded, of great substance, and  $2\frac{1}{2}$  inches across. The colour is a bright vermilion, quite dazzling when seen in the sunlight, and the plant being dwarf in habit and very floriferous renders the variety one of great excellence. Another beautiful novelty is Annie Laing, which has already been exhibited on several occasions, and received the honorary distinction of certificates. It has flowers of exact symmetrical form, of good substance, the petals round and bright rose pink, one of the most distinct shades that have yet been produced. Mrs. Robert Whyte has also been accorded similar honours to the above this year; it has peculiarly rich, rosy crimson-coloured flowers very abundantly produced, and the compact habit of the plant is moreover an additional recommendation. Mrs. Highgate is in some respects suggestive of the well-known and highly valued variety Lady Hume Campbell, but there is more of a salmon tinge in the well-formed flowers, and these are borne in great profusion. Two new varieties of the Davisi type are Commodore Foot, which bears attractive rich crimson flowers, similar to those of its principal parent but larger and brighter in colour; and General Mite, with orange-tinted blooms. Both are dwarf, compact, and free in flowering, and would be useful for employing as a marginal line to larger-growing varieties, or in positions where the others would be unsuitable. Among the finest of the older forms Lady Hume Campbell, already referred to, well holds its position as a floriferous variety of excellent habit, and scarcely surpassed in the

rose tints. Mrs. Laing is an unrivalled white-flowered variety as grown at Forest Hill, very pure, of fine substance, and good rounded form; while Stanstead Royal, the progenitor of so many large-flowered varieties, is noteworthy among the forms with scarlet flowers. Many others are also indispensable in forming a collection, but those desirous of making a selection have every opportunity of doing so in exact accordance with their particular tastes, either at the nursery or the exhibitions, where the collections produce such bright displays.

The double-flowered varieties, like the others, have also many

admirers, and accordingly a house is devoted to them, all the best being represented. But the two leading forms are Comtesse H. de Choiseul and Davisi flore-pleno superba, the former having been in commerce some time, and the latter having appeared this season. Comtesse H. de Choiseul has flowers of moderate size, but quite full of petals, and of much better form than that characterising the majority of double varieties. There is a curious transition of colour as the flower advances in age, gradually changing from white to rosy pink or salmon. The "superb" form of the double Davisi well merits its name, for while pos-

Fig. 118.—NEPENTHES AMPULLACEA.

sessing the rich colour of the type the flowers have the numerous petals disposed with great regularity, imparting a symmetrical and refined appearance to the blooms. This has already been certificated at Kensington and elsewhere. A new double white named Campanulæflora is also noteworthy, the flowers being of very satisfactory substance and purity. Esther, rose; Flammea, crimson; Gloire de Naney, vermillion; Dinah Felix, red, white centre; and Marie Bonchet, of quite a purplish tinge, were in fine condition among many seedlings of more or less beauty.

To conclude these brief notes the following varieties may be mentioned as well adapted for culture in baskets, and when well treated Tuberous Begonias in baskets are attractive additions to

a conservatory or intermediate house. Most of the slender-growing forms are suitable for the purpose, but the following four are found to be generally useful—Violacea Mrs. Wills, Purple Emperor, and Massange de Louvrex.—VISITOR.

#### NEPENTHES AMPULLACEA.

RARELY is such a compact and handsome specimen seen of this Pitcher-plant as the one represented in the accompanying woodcut. This plant growing in a 6-inch pot was greatly admired by all visitors to Messrs. Veitch & Sons' Chelsea nursery early in the present year. Were it possible to ensure results so satisfactory

few would grudge any time and labour requisite for the desired end, but the majority of cultivators must be content with a more limited amount of success, and the most judicious treatment might fail to produce so well furnished a plant as that shown in the figure. Fortunately, however, *Nepenthes ampullacea* is not more difficult to grow than its relatives, tropical heat, abundant moisture, and a light compost of peat being its chief requirements, and if a good crop of pitchers be developed the plant becomes one of the most interesting in its family. Even though the pitchers lack the brightness of colour and peculiarity of marking distinguishing some *Nepenthes*, they possess other recommendations, being very neat in form, and the plant is dwarf and compact in habit. Indeed compared with *N. bicalcarata* and similar large forms it is quite a pigmy, and perhaps on this account is the more attractive by the force of contrast. Wherever the curiosities of the vegetable kingdom are valued this *Nepenthes* should obtain a place, as it will unquestionably be admired if carefully grown. As a table plant the specimen figured was quite unique.

#### HAMPERS AND BOXES.

It is a question if any appliances of the garden cause more trouble and annoyance to both employers and gardeners than these. An employer naturally thinks that if he sends a present of flowers, plants, or fruit, and has also purchased the hampers and boxes for sending them, that these should be promptly returned; and gardeners feel extremely annoyed when they find they can only use a hamper or box once, and have others to buy, beg, or obtain as best they may, because of the forgetfulness of people to return what has been lent to them. There are people who possibly think it is a small matter to retain a hamper from a nobleman to whom such an article is considered insignificant, but when a hundred are sent and not a tithe returned the matter ceases to be a small one, but, on the contrary, is of great importance, as many ladies, gentlemen, and gardeners know to their cost or disappointment. The least that anyone can do when they receive a gift is to return the article in which it is conveyed, as it affords the means of themselves and others receiving similar presents the sooner. The articles, however, ought to be returned on higher grounds—the grounds of right and justice. I hope if any readers of these lines have hampers or boxes that do not belong to them they will return them at once, and they will be gratefully received by more than one—VICTIM.

#### HOW SHALL WE MANAGE OUR BROCCOLI CROP?

I HAVE no doubt that through the severity of the past two or three winters, and the almost total failure of the Broccoli crop in consequence, the above question has passed through the minds of many gardeners who like myself have a large family to supply. As this vegetable is rather an important one in most places, it will be as well to discuss the possibility of getting better results by a different system of cultivation, or I ought to say, to try and improve upon the present one. It is perfectly clear to all that out of the many different varieties of Broccoli in cultivation there is not one that can be selected to go through the rigour of our winters unscathed. Considerable space may be occupied and much time and labour bestowed, yet the uncertainty of a crop remains the same. I have thought much on the matter, and conclude that some good may be done by paying more attention to details of cultivation, and not carry it out in that rough-and-ready way so much in practice now-a-days. I am of opinion that as a rule the seed of many crops is sown much too early and too thickly, and the plants are often allowed to stand in the seed bed too long, so that they suffer much when planted out. They should be pricked out early, whereas many times they are not pricked out at all. When finally planted out a much greater distance should be allotted them than is usually the case. I also think that as a rule Broccoli is grown much too luxuriantly, and instead of being planted in the richest garden soil one of very moderate quality is the best, of a more firm and tenacious character if possible rather than light and rich. If there is no alternative the soil should be made much firmer about the plants than is the custom. The object should be to grow them dwarf and slow, so that the tissues of the stem and leaves should be more hardy instead of soft and fleshy. It is not uncommon to see those plants that are dwarfest and at the outside of a plantation stand the longest. It often happens, too, that market gardeners who have to grow their Broccoli in the open fields are much more successful than gardeners where, from the positions of their gardens, the plants are much more encouraged in the early stages of their growth.

The year before last I saw a field of ten acres of Broccoli in the month of April, when very few had failed to stand the winter,

though most of the gardeners in the neighbourhood had lost their crops. This field was manured and planted with Peas, and the ground well cultivated between the rows. After the crop was cleared off the soil was well horse-hoed and cleaned, and the Broccoli planted out. Owing to the ground being hard at the bottom the plants grew very dwarf; none of the stems appeared to exceed 9 inches out of the ground. The man to whom they belonged said his plan was always to grow the plants on a hard bottom, but to well cultivate the surface. This is the plan that I want gardeners to try in the coming season. I am aware that there are some sorts of Broccoli much hardier than others—those must grow; and although we may not succeed in securing full success, we may at least prevent such a blank as we have had this spring in this all-important crop.

There are some very excellent varieties of recent introduction, but there are some old sorts which I should put more confidence in if I could obtain them true. Miller's Dwarf Russian is one, and Macfarlane's, or what some called Leslie's Late White, is another, some of which I never failed to save over the winter. I took a prize with the last-named at the International Exhibition in 1866, but have been unable to obtain it since. I grew the above two sorts when living in Suffolk in that severe winter of 1860 and 1861, and I think they were the only two which gave us some good cuttings in the following spring.—THOMAS RECORD.

#### BOUVARDIA ALFRED NEUNER.

It will be satisfactory to those who have purchased, or who intend purchasing, plants of the double *Bouvardia* which has received so much attention lately, to learn that the first flowers produced in England during the past week fully maintain the descriptions of the plant received from America. The flowers are fully as double as those shown in the woodcut on page 417 of this Journal, consisting of two or three corollas with from eight to a dozen pointed lobes arranged in a star-like manner, the inner whorl alternating with the outermost, and when the third is present the lobes of that are alternate with those of the second. There is not the slightest approach to contortion or deformity in the flowers we have seen, but, on the contrary, the most exact symmetry prevails; moreover they are pure white, of good substance, and are borne in moderately large dense trusses. The best example that has come under our observation is Messrs. H. Cannell & Sons' nursery at Swanley, where a specimen in a 48-size pot is bearing four fine trusses of flowers such as we have described; the plant also appears to be of vigorous yet compact habit, and as floriferous as many of the single forms. Messrs. J. Carter & Co. also have plants in flower at their Perry Hill nursery, and no doubt visitors to the London horticultural exhibitions and the meetings of the Royal Horticultural Society will soon be familiar with the latest addition to the list of double-flowered plants.

#### BRIEF NOTES FROM CHISWICK.

THE Royal Horticultural Society's Gardens are now very attractive, although the beauty of the fruit trees has faded for the season. Plants both outside and in the houses are in excellent condition, and much that is interesting may be noted.

*Ivy-leaf Pelargoniums*.—Most sections of *Pelargoniums* are largely represented at Chiswick, and of recent years the attention paid to the Ivy-leaf forms has led to the collection being greatly extended, all the best varieties in commerce being now included. Of the double varieties the best are Gloire d'Orleans, bright rose, fine truss, very free, compact habit; Sarah Bernhardt, bright pink and white, pretty; A. F. Barron, mauve pink, large compact truss; Astre, purple; Robert Fortune, similar to Gloire d'Orleans but a little darker; M. Dubus, very bright rose, excellent colour; and Mdle. Jeanne Wouters, which received a certificate a fortnight since at Kensington as seedling 29. The flowers are large, of a fine pink tinge, and the truss is also large and compact. Among the single varieties La Vesuve, scarlet; Bridal Wreath, white, crimson centre; and Alice Lee, of a scarlet shade, were the most noticeable.

*Pelargonium tricolor*.—The groups of old forms and species of *Pelargonium* occasionally shown at Kensington from this garden are invariably much admired, and it is surprising that some of these almost forgotten sorts are not brought again into general cultivation. The one named above and represented in fig. 119 is now flowering freely, and though comparatively scarce in gardens of the present day it was highly valued half a century and more ago. In 1796 the following remarks accompanied an accurately coloured plate in the "Botanical Magazine," and is of especial interest as showing the opinion then held of it:

"The *Pelargonium tricolor*, a species perfectly new in point of beauty, is thought to eclipse all that have hitherto been introduced to this country. Its blossoms are certainly showy, and in a collection of plants they are the first to attract attention. The two uppermost are dark red, nearly black; the three lowermost are white, hence the name of tricolor. This peculiarity of colour joined to their form has induced some to fancy a similarity betwixt its flowers and those of the Heartcase; to the flowers of *Lathyrus articulatus* in form and colour they also bear a distant resemblance." It deserves to be grown more extensively than is the case now, as the flowers are well suited for cutting, and they can be employed in buttonholes with admirable results.

*Tuberous Begonias*.—A beautiful display of these popular plants is observable in one of the houses. Many fine seedlings are included that bid fair to take honours among the novelties of the year. Good substance, bright colours, and excellent form characterise the majority, the effects of good culture being also evident in the vigorous growth and healthy appearance of the plants. Large pots are eschewed, none exceeding 8 inches in diameter—a

Fig. 119.—*Pelargonium tricolor*.

point of great importance too often neglected, for however fine a plant may be, if the pot be out of proportion to its size the effect is clumsy in the extreme.

*Gloxinias*.—These constitute another feature, and are similarly deserving of commendation. Among them, too, are several handsome seedlings of the semi-erect-flowered section, which now appear to be more generally liked than those with pendulous flowers. The advantage of the former is that a full view of the corolla is obtained, and consequently the colour, form, and marking are much more clearly observed. The flowers are generally large without being coarse, and several instances the colours are very delicate and bright.

*Hardy Plants*.—Numerous attractive plants are flowering in the borders and on the rockery, not the least beautiful being the English and Spanish Irises, or Xiphions, as they are now termed. Among the former are several fine varieties, the flowers of which are rich blue or purple, of massive form and very imposing, while the latter are distinguished by the peculiar combinations of tints marking the flowers, some being characterised by hues that for peculiarity are only rivalled in the great Orchid family. Iberises, too, are fine, especially that useful form *I. Garreuxiana*, which is a mass of its white blossoms. Around one bed is a band of a very humble but none the less pretty plant—viz., *Thymus rotundifolia*; the small bright purplish blossoms being

produced so freely as to quite conceal the foliage. Other plants are noteworthy, but these remarks may be brought to a conclusion by referring to—

*Gillenia trifoliata*, of which the woodcut (fig. 121, page 535) represents a flowering spray. It is a North American plant included in the great Rose family, and usually attains a height of 2 feet, being compact in habit and flowering freely. The leaves are formed of three leaflets, as the name implies, each being pointed and serrated at the margin. The flowers have five white linear petals, and are borne in loose panicles at the upper part of the stem. It frequents damp and boggy places in its native habitats, but it is not particular under cultivation, almost any light well-drained soil suiting it. The plant cannot be described as one of the most showy, but the slenderness of the stems and flowers impart a degree of elegance to it that entitles it to some consideration.—L. C.

#### TRADESCANTIA VIRGINICA.

It may not be generally known that this is one of the finest hardy herbaceous plants for town gardens that can be grown, and the bright violet-blue flowers with yellow stamens are extremely beautiful. Its flowers are most suitable for cutting and placing in vases, as they continue fresh for weeks when the stalks are placed in water; or rather fresh flowers expand the same as those of *Gladioli* do. The plants thrive in almost any kind of soil provided they have plenty of water, and they will well repay for a liberal application of liquid manure twice a week if the soil is poor. I have a number of plants in my brick-enclosed garden, but none at the present moment is so satisfactory and useful as this *Tradescantia*. It is so hardy that no amount of frost injures it, while no insects attack it, no smoke appears to check the growth, and whether the weather is cold or hot it never fails to produce a long supply of its very bright and attractive flowers. In all gardens this old plant should be grown, but for town gardens especially it is admirably adapted, and flourishes as well in summer there as *Chrysanthemums* do in the autumn. It is readily increased by division; and early spring, just as the young growths appear, is a good time for replanting.—A CITY MAN.

#### NOTES AND GLEANINGS.

TO OUR READERS.—The preface, with the index to the present volume, will be published with our next issue, which will also contain a portrait of the founder of the *Cottage Gardener*, Mr. G. W. Johnson, who relinquished his editorial duties some time ago to seek the rest he has so well earned.

— AS usual the EVENING FÊTE OF THE ROYAL BOTANIC SOCIETY, which was held on the 22nd inst., proved very successful, the floral decorations and groups producing a brilliant display, and a large number of visitors assembled although the night was cold for the season. Nineteen classes were provided for dinner-table decorations, cpergnes, bouquets, baskets of flowers, and groups of plants. In several the competition was keen, and in the majority very satisfactory exhibits were staged. The chief prizes were awarded to Messrs. W. P. & G. Phillips, Oxford Street; Mrs. Henderson, Hamilton Terrace; Mr. W. Wood, Conduit Street; Messrs. Dick Radclyffe & Co., Holborn; Miss Gardener, St. John's Wood Park; Mr. Buster, St. Mary's Cray; Mr. J. Prewett, Hammersmith; Miss A. Williams, Holloway; Mr. W. Brown, Richmond; Messrs. Henry & Co.; and Mr. G. Wheeler, St. John's Lodge, Regent's Park.

— AN amateur cultivator submits the following IMPORTANT ADVICE TO PURCHASERS OF PANSIES—"During the past May and the present month Scottish nurserymen have been flooded with orders for Pansies from the south. Of course they are glad to sell their stock, but they would be better satisfied were the orders to reach them in autumn or early spring, when the plants would give their customers that satisfaction which all respectable

vendors like to hear their goods have given. As it is, it can only be through careful management that plants purchased in early summer will get established in the south at all; and as to blooms either like or in the least approaching to the same varieties when well grown, that is simply out of the question. Those who have purchased so late ought not therefore blame the vendors where such Pansies have not succeeded to their expectations."

— WE regret to have to record the DEATH OF MR. S. M. CARSON, formerly gardener to Mr. T. Farmer at Nonsuch Park, Cheam, where he attained much celebrity as a plant grower and exhibitor. He was a native of Gatehouse of Fleet, in Kirkcudbrightshire, and after filling several positions of varying importance he took charge of the Orchids and stove at Messrs. Lodiges' Hackney nurseries; thence he proceeded to Nonsuch in the capacity of head gardener and bailiff, which duties he performed until 1872, when he retired on an annuity generously allowed him by his employer. Mr. Carson was sixty-seven years of age at the time of his death.

— "G. H." writes—"Will any correspondent of the *Journal of Horticulture* kindly give the experience as to the best methods of EXTERMINATING WIREWORM from a garden?" Possibly some of our readers can give the information desired.

— CAULIFLOWERS seem to thrive at the Cape, where, according to the *Cape Argus*, a seedsman has been exhibiting three which weigh together 80 lbs.

— THE IPSWICH HORTICULTURAL SOCIETY'S Summer Show will be held on July 5th in Christchurch Park, Ipswich, and the Autumn Show at Holy Wells on September 2nd. There are seventy-four classes in the schedule, apart from cottagers' prizes, and sixty-four in the latter. Among a long list of donors of special prizes we observe that Mr. Kingdon offers a silver cup, value £5, in the amateurs' class for twenty-four Roses. In the open class for forty-eight Roses the chief prize is £5.

— MESSRS. J. CARTER & Co. have now an extremely fine display of PETUNIAS AT PERRY HILL, where in several long span-roofed pits between twelve and thirteen thousand plants are flowering. Very careful selection of seed has been made, and as the result the flowers exhibit a greater diversity and brightness of colours than we have yet seen. From the above large number of plants the least promising are being removed, only the most distinct and beautiful being retained for yielding seed, so that the strain is likely to become an unusually good one. The single varieties are particularly notable for the rich tints they represent, some of the crimson and purple hues possessing a remarkable depth and clearness, in some cases approaching maroon in intensity. Rose and white selfs are also included, others being striped with crimson or pink on a light ground, the markings very evenly defined, or in still other instances the corollas are covered with a delicate lacing of purple and crimson on a pale lavender or white base. Doubles are similarly good, very full, substantial, in some cases having deeply fringed margins, and in others, more peculiar but less pretty, the edge is green and the body colour pink or crimson. Such an extensive and admirable collection of these plants is rarely seen in the neighbourhood of the metropolis.

— THE "American Cultivator" has the following relative to the APPLE CROP OF MASSACHUSETTS:—"Respecting the great Apple crop of Massachusetts last year the town of Shrewsbury stands high in quantity of Apples produced. Having a soil specially adapted to Apple culture, and a population that has given the subject much attention, the Farmers' Club recently through a committee canvassed the town for facts and figures. The committee's report gave as the product for 1880, 30,000 barrels of marketable winter Apples exclusive of the fall fruit; also 15,000 to 20,000 bushels which went to the cider mills. There

are about thirty farmers in town who produce 400 to 500 barrels of Apples each per annum. A few raise a larger quantity, say 600 to 800 barrels, but none as high as 1000 barrels. Of the 30,000 barrels noted above nine-tenths were Baldwins."

— IN Mr. Birbeck Hill's volume, recently published by Messrs. De La Rue & Co., entitled "Colonel Gordon in Central Africa," it is stated that the wealth of one of the districts referred to consists of Fig trees, which are owned by individuals, and eighty of them make a very rich man. The trunks get hollow, and storms fill them with water. Some of the trees will hold a ton and keep it pure and fresh. They are the reservoirs of a thirsty land. Ants too, which are very numerous, contribute to the water supply by forming hollows with means to conduct the rain into them, and so keep reservoirs of water in dry seasons.

— RELATIVE TO GROWING MUSHROOMS IN CAVES, the following appears in a daily paper:—"An enterprising Frenchman, remembering what is done in underground Paris in the way of Mushroom cultivation, has proposed to take a lease of a portion of the Mammoth Cave in Kentucky with the view of raising regular crops of the nutritious and delicious fungus. As the cave contains many square miles of underground passages, none of which are shown to visitors because there is nothing attractive in them, the authorities will probably accept the Frenchman's offer, and lease the "Great Bat Room" to him for the purpose of growing Mushrooms. This passage, formerly known as Audubon's Avenue, was not long ago a resort of "consumptives," who resided in cottages built near the entrance, the pure air and the equable temperature being supposed to compensate for the absence of sunlight and the sights and sounds of the busy world. A very short time sufficed to explode that fallacy, and it is now probable that the uninteresting portions of the cave will be devoted to the culture of Mushrooms, for which they are admirably adapted."

— A CORRESPONDENT of the "Irish Farmers' Gazette" has submitted the following dimensions of CONIFERS AT WOODSTOCK, KILKENNY:—*Araucaria imbricata*, height 52 feet, diameter of branches 29 feet, girth of stem 3 feet up 7 feet 1 inch; *Cryptomeria Lobbii*, height 44 feet, diameter of branches 18 feet, girth of stem 4 feet 2 inches; *Cupressus macrocarpa*, height 58 feet, diameter of branches 48 feet, girth of stem 8 feet 6 inches; *Picea cephalonica*, height 58 feet, diameter of branches 44 feet, girth of stem 8 feet; *Pinus insignis*, height 66 feet, diameter of branches 43 feet, girth of stem 8 feet 10 inches; *Pinus strobus* (Weymouth Pine), height 65 feet, stem clear of the branches 57 feet, girth 7 feet 7 inches. The largest common Silver Fir is 107 feet in height, diameter of branches 59 feet, girth of stem at 4 feet from the ground 14 feet 9 inches.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 28TH AND 29TH.

THE annual Rose Show of this Society being held in conjunction with the Exhibition of the Pelargonium Society produced, as was expected, a display of considerable beauty and extent. Not only was the long tent occupied as last year with the Roses and Pelargoniums, but the large marquee employed at the recent Show was also called into requisition, and though this was not crowded yet sufficient was contributed to produce an admirably effective display. The Fruit and Floral Committees' duties were comparatively light, but several interesting plants and some fine Melons were submitted to their consideration.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. Six Melons were exhibited, a fine example of Highcross Hybrid being shown by Mr. T. Hopkins, The Gardens, Highcross, Framfield, Sussex, for which a first-class certificate was awarded. It is a green-flesh variety, very solid, of good flavour, and well netted, the fruit being above the medium size. Mr. C. Howe, The Gardens, Benham Park Newbury, sent a scarlet-flesh seedling, the result of a cross between Queen Emma and Read's Scarlet-flesh; it was of good form and colour. Mr. G. Abbey, gardener to C. N. Palmer, Esq., M.P., Grinkle Park, Yorkshire, had a fine fruit of a green-flesh variety superbly netted. Mr. Carmichael,

The Gardens, Nowton Court, and Mr. C. Ross, Welford Park, Newbury, also sent Melons, the former not considered sufficiently distinct to merit an award, and the latter arrived too late. Mr. G. Thompson, gardener to C. Lee, Esq., Croxby House, Hounslow, sent two fine bunches of Madresfield Court Grapes. A cultural commendation was awarded. Mr. G. Miles, The Gardens, Wycombe Abbey, Bucks, was accorded a vote of thanks for a fine dish of Stamfordian Tomatoes, and a similar award was granted to Mr. W. Ward, Longford Castle, Salisbury, for fruits of the same variety but not so even. Mr. R. Gilbert, The Gardens, Burghley, had a dish of Peaches, "The First Lord," of moderate size and apparently ripe. Mr. H. Eckford, gardener to Dr. Sankey, Sandywell Park, Cheltenham, exhibited fruits of a small Cucumber named Climax, very even, and bearing good bloom. A vote of thanks was accorded. Messrs. J. Veitch & Sons sent examples of their Extra Early Forcing Cauliflower, which had heads of moderate size and very white, and deserved the certificate awarded. It was stated that seed of this and the Early London Cauliflower were sown February 14th of the present year, and at this time the latter shows no sign of heading. Mr. Thomas Piper, Maresfield, Sussex, was accorded a vote of thanks for examples of his Golden-podded Broad Bean, the pods being small but of a yellow colour when ripe. Mr. R. Dean, Ealing, sent a seedling dwarf Pea, a cross between Laxton's Unique and Dean's Dwarf Marrow. Mr. Miles had specimens of Suttons' New Mammoth Cos Lettuces; and Mr. Gilbert Suttons' Marvel Cabbage Lettuce, both fine.

**FLORAL COMMITTEE.**—J. McIntosh, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, exhibited a group of new plants, among which the following were noticeable—*Juncus zebrinus*, the Variegated Reed; *Amaryllis* The Syren, a variety with finely formed flowers, bright scarlet; *Impatiens* Mariana, a dwarf form with small leaves variegated with white and green; *Globba coccinea*, a peculiar zingiberaceous plant with spikes of bright scarlet wax-like flowers and dark green elliptical leaves; *Styrax serrata*, one of the Benzoin family, with ovate bright green leaves and pendulous white flowers; *Astilbe Thunbergi*; the handsome *Spiraea* previously described; *Vitis heterophylla* variegata, and several others which were certificated. Mr. Croucher, The Gardens, Sudbury House, Hammer-smith, sent several Orchids, among which were a fine *Odontoglossum vexillarium* atro-roseum with two spikes of seven flowers each, very large and deeply coloured, for which a cultural commendation was awarded, and a specimen of *Lycaste Deppei* splendida with about twenty flowers. Messrs. Downie & Laird were accorded a cultural commendation and a vote of thanks for a stand of very handsome seedling Fancy Pansies. Messrs. H. Cannell & Sons, Swanley, had a basket of the double *Mimulus* Beauty of Sutton, and a specimen of the double white *Bouvardia* Alfred Neuner, described in another column. W. H. Tillet, Esq., Sprouston, Norwich, was accorded a vote of thanks for spathes of *Philodendron Sellowii*, very fine.

First-class certificates were accorded for the following—

*Sobralia xantholeuca* (Veitch).—A species of good habit, the stems being of moderate height and clothed to the base with tapering bright green leaves. The flowers are of a very delicate pale yellow tint, and contrast strikingly with the better-known *S. macrantha*.

*Phalenopsis violacea* (Veitch).—A pretty dwarf species with small violet purple-coloured flowers, very distinct in form from many of the genus. The leaves are bright green, smooth, and shining.

*Juncus zebrinus* (Veitch).—A second-class certificate was awarded for the variegated Rush, which has been frequently described in these columns.

*Agave Parryi* and *Yucca Peacocki* (Croucher).—These have been previously certificated by the Royal Botanic Society, and were described on page 375 of the present volume.

**SCIENTIFIC COMMITTEE.**—*Rose Leaves*.—Mr. W. G. Smith reported upon the Rose leaves exhibited at the last meeting, and found no fungi nor insects, but attributed the injury to over-manuring.

*Melon Shoots Diseased*, referred to Mr. Smith for report, were found to be attacked by red spider, acari, nematoid worms, earwigs, &c., which quite accounted for the malformed growth.

*Birch Tree*.—Mr. A. W. Bennett exhibited a vigorous and remarkably hairy shoot from a nearly dead Birch tree, received from Mr. Newman of York Grove, Peckham.

*Campanula Hybrid*.—Mr. G. F. Wilson exhibited a specimen supposed to be a hybrid between *C. pulla* and *C. carpatica*. The foliage was remarked as not being like *pulla*, and Sir J. D. Hooker raised doubts as to its being a hybrid. It was referred to Kew. Mr. Wilson also remarked that *C. nobilis*, *C. alba*, and *C. punctata* were in blossom simultaneously at Weybridge, received from M. Froebel of Zurich. The flowers of *C. nobilis* and *C. punctata* were very distinct in shape, those of *C. nobilis* being very long, and of *C. punctata* bulged out in the middle.

*Iris spectabilis* (*Xiphion vulgare*).—Dr. M. Forster exhibited a malformed flower of this plant, in which the styles had become arrested. The ovary was well developed.

*Coleus Infested by Dodder* (*Cuscuta* sp.).—A specimen was exhibited from Mr. Carter, the parasite having been grown with the plant.

*Gladioli*.—Rev. H. H. Crewe exhibited four forms of *Gladiolus*—viz., *G. illyricus* from the New Forest, *G. triphyllus*, *G. segetum*, and a species found growing in profusion in wet meadows at Gijon (North Spain) associated with *Corbularia citrina*, *C. bulbocoides*, *Narcissus biflorus*. It was referred to Kew. Mr. Crewe doubted whether to refer it to *G. byzantinus* or *G. communis*.

*Mint Fungus*.—Mr. W. G. Smith exhibited specimens of garden Mint infested with the Mint fungus, *Æcidium Menthae*. Mr. Smith stated that as far as his experience went the fungus was chiefly confined to garden Mint. Just now the fungus is extremely common on the Mint exposed for sale in the greengrocers' shops of London.

*Gooseberry Fungus*.—Mr. Smith exhibited fruits and leaves of Gooseberry badly attacked by *Æcidium Grossulariae*. The fungus appears to be widespread and virulent this season, destroying the fruits.

*Primitive Agriculture and Bread-making*.—Mr. Smith showed a hoe mounted with a withy; the blade, 8 inches long, being made of flint. The same instrument if inverted and drawn along the ground by a man would act (when guided with a second withy) as a primitive plough, and make a good furrow. Mr. Smith also exhibited an ancient British millstone together with the flint corn-crushers or mullers as used with it by the primitive inhabitants of this country in preparing the bread made from the small-eared Wheat that was cultivated by them. He also showed a block of iron pyrites and a stone with abraded ends for lighting the fire to cook the wheaten bread, and a knife blade 5½ inches long made of flint, used in ancient times for cutting up food and for other purposes. The same gentleman also showed spindle whorles made from drilled pebbles, such as were used for weaving in ancient British times. The objects had been mostly found by Mr. Smith himself in British camps in this country.

## THE ROSE SHOW.

THE Roses taken collectively were better and more numerously exhibited than might have been expected to be, many growers not being forward enough to cut sufficiently to exhibit. Mr. Turner's were his first this season, and more successful he could not well have been, for he obtained the first prize in every class in which he competed. His blooms could not be said to have that breadth and substance of petal we are accustomed to see, but they were remarkably fresh and bright. Messrs. Curtis, Sandford, & Co.'s blooms were in some instances larger, but in others lacking the variety and freshness of Mr. Turner's. Other trade exhibitors were not up to their usual standard of merit. The first-prize stand of twelve exhibited by Mr. Ridout, gardener to B. Hayward, Esq., was the finest flowers in the Show, and the collections of Teas exhibited both by the trade and amateurs were very praiseworthy.

Class 1, forty-eight Roses, distinct, single trusses, there were six competitors. Mr. Charles Turner was awarded the first prize with fair examples of *Madame Nachury*, Duke of Edinburgh, Miss Hassard, Prince Arthur, Edward Morren, Horace Vernet, Marquise de Castellane, Sir Garnet Wolseley, Villaret de Joyeuse, Elie Morel, Charles Lefebvre, Madame H. Jamain, Le Havre, Oxonian, Madame Victor Verdier, François Michelin, Comtesse de Serenye, Ferdinand de Lesseps, La Rosière, Maréchal Niel, Nardy Frères, Mrs. Harry Turner, Margaret de St. Amand, Prince Camille de Rohan, very fine indeed; *Perle des Jardins*, Sénateur Vaisse, Niphetos, Charles Darwin, Peach Blossom, Marie Baumann, Duke of Wellington, Marguerite Brassac, Bessie Johnson, Madame Marie Verdier, Dr. André, Mdle. Eugénie Verdier, Camille Bernardin, Constantin Tretiakoff, Elise Boëlle, Devienne Lamy, Star of Waltham, Baroness Rothschild, John Bright, Duchesse de Morny.

Messrs. Curtis, Sandford, & Co. were a very close second indeed with a collection of well-built flowers, containing amongst others *Madame Gabriel Luizet*, Etienne Levet, Beauty of Waltham, Sénateur Vaisse, Le Havre, Madame Ducher, new; Alfred Colomb, François Michelin, grand; Marie Baumann, fine; Duchesse de Morny. Mr. B. R. Cant, Colchester, third with a very fair collection.

For twenty-four Roses, distinct, three trusses of each, there were four collections, the post of honour again falling to Mr. Turner, closely followed by Messrs. Curtis, Sandford, & Co. and Mr. Cant, who were second and third respectively. Général Jacqueminot, Duke of Edinburgh, Mrs. H. Turner, Sénateur Vaisse, and Marguerite Brassac were very fine among the dark and red varieties; Marguerite de St. Amand and Marquise de Castellane in the pinks; and three beautiful blooms of the delicate white Tea Niphetos stood out most conspicuous. *Magna Charta* and *Madame Gabriel Luizet*, Mdle. Eugénie Verdier and Beauty of Waltham were very fine in the second-prize collection; and A. K. Williams, Etienne Levet, and Duke of Wellington were the most noticeable in Mr. Cant's third-prize stand.

In the class for twenty-four Roses, distinct, single trusses, there were five competitors staged. Mr. Turner here again, as in the other two classes, was awarded the first prize for a very even and bright collection, containing many of the same varieties as named in his other two first-prize collections. For twelve Roses, distinct, Messrs. Turner, Cant, Piper, Bunyard & Co., and Rumsey were the exhibitors, the prizes being awarded in the order of their names.

There were only three collections of twelve Teas, distinct, which is not surprising after the severe winter they have had to encounter; Mr. Piper being a very good first with *Souvenir d'un Ami*, Jean Ducher, Madame H. Jamain, Marie Van Houtte, *Souvenir de Paul Neyron*, Comtesse Riza du Parc, Marie Opoix, Catherine Mermet, Safrano, Niphetos, Josephine Malton, Marie Guillot. In Mr. Cant's collection *Anna Ollivier*, *Devoniensis*, *La Boule d'Or*, Comtesse de Nadaillac were very fine. Messrs. Paul & Son, The Rose Nurseries, Cheshunt, were third, having a very fine bloom of *Archimede*. The interest taken in these Roses is so intense that visitors linger around them in admiration for a length of time. Messrs. Curtis & Co. were

first with six Roses of any sort of Hybrid Perpetual with magnificent blooms of François Michelin, Mr. Cant second with the lovely bright A. K. Williams, and Mr. Bunyard third with Marie Baumann. Mr. Cant is the only exhibitor for six Teas of any sort Tea or Noisette, and was awarded first prize for a stand of fine Devonensis.

In the classes devoted to amateurs there was a very fair competition. J. B. Haywood, Esq., Woodhatch Lodge, Reigate, was awarded the first prize in the class for twenty-four, distinct, with Marquise de Castellane, Antoine Ducher, Thérèse Levet, Edouard Morren, Madame C. Crapelet, Countess of Rosebery, La France, Etienne Levet, Ferdinand de Lesseps, François Michelin, Le Havre, Abel Grand, Marie Baumann, Mrs. Baker, Countess of Oxford, Charles Lefebvre, Sénateur Vaisse, A. K. Williams, Duke of Edinburgh, Louis Van Houtte, Madame Victor Verdier, Abel Carrière, Général Jacqueminot. The second prize fell to Mr. John Hollingworth, Turkey Court, Maidstone. G. P. Hawtrey, Esq., Aldin House, Slough, was placed third. A very fine bloom of Mdle. Marie Verdier was very conspicuous for its beauty in this stand. There were seven collections.

For twelve Roses, distinct, three trusses of each, Mr. Hollingworth was again a very good first with large and well-built flowers of the following varieties—Ferdinand de Lesseps, Miss Hassard, Marquise de Castellane, Dupuy Jamain, Avocat Duvivier, La France, Madame Gabriel Luizet, Camille Bernardin, Sénateur Vaisse, Mons. E. Y. Teas, and a dark red variety named Princess of Wales. Mr. Joseph Davis, The Square, Wilton, Salisbury, received the second award; and Mr. E. Berry, gardener to the Countess of Leven and Melville, Roehampton House, Roehampton, the third. Five competitors. In the class for twelve, distinct, Mr. Haywood was again a good first; Mr. Joseph H. Pemberton, The Round House, Havering-atte-Bower, Romford, second; and Mr. Charles Davis, The Grammar School, Aynhoe, Banbury, third, all exhibiting well. Seven collections staged. In the class for twelve Roses, distinct, Tea or Noisette, the amateurs outdone the nurserymen in point of number of competitors, there being five collections against three in the corresponding class for the trade. Mr. Joseph Pemberton was a very good first with Homère, Belle Lyonnaise, Souvenir d'un Ami, Madame Willermoz, Bouquet d'Or, Jean Ducher, Madame Bravy, Madame Berard, Rubens, Maréchal Niel, Perle des Jardins, Karoline Kuster. Mr. Charles Davis takes the second prize with a fine lot, having amongst others a very fine-shaped flower of Bouquet d'Or. Mr. Hollingworth third.

For six Hybrid Perpetuals (amateurs) Mr. E. Berry took first prize with François Michelin, Mr. Pemberton second with Souvenir de Pierre Dupuy, a somewhat rough-petaled Rose as shown, and Sir Trevor Lawrence third with Pierre Notting. In the class for six Roses of any sort Mr. Davis was awarded the first prize for six lovely blooms of Bouquet d'Or, Mr. Hollingworth being second with Caroline Kuster, and Mr. Pemberton third.

For six new Roses of 1878 and 1879 Mr. Turner obtained the first prize with Duchess of Bedford, Charles Darwin, Countess of Rosebery, Mrs. Harry Turner, Madame Eugénie Verdier, and Paul Jamin. Mr. Cant was placed second with A. K. Williams, Pierre Carot, Duke of Teck, Bennett's Hybrid Teas Duke of Connaught, Jules Chrétien, and Duchess of Westminster, this latter possessing very much the same depth and substance of petal as Mons. Noman but of a deeper cerise colour.

There were several contributions not for competition, among them being the following—Six boxes of Roses were staged by Mr. Prince, Oxford, three of them containing a large quantity of Moss Roses in variety, and the remainder some beautiful Teas. Mr. Rumsey of Waltham Cross also contributed a large collection of cut Roses, some beautiful buds of Teas, and a box crowded with the old or common Moss Rose was particularly worthy of notice. Messrs. Paul & Son sent 150 Roses in pots, which at this season of the year were a great attraction. These plants were only from 1 foot to 18 inches high, and carried from four to ten flowers, and were deservedly awarded the large silver Flora medal. They consisted of the most popular varieties, among which we noticed a pure white sport of Baroness Rothschild, being of more substance than Mabel Morrison, which is also a sport of this popular Rose, but is unfortunately too thin for any purpose, but Mr. Paul's white sport promises to become a useful Rose that is much needed.

**GROUPS.**—The Society offered three prizes for the best arranged group of plants occupying a space not exceeding 300 square feet. Three competitors appeared, Messrs. W. Cutbush & Sons, Highgate, being accorded the first prize for a very tastefully arranged group consisting chiefly of fine-foliage plants, such as Dracænas, Palms, Maples, and Ferns; and perhaps the only objection that could be urged against it was the comparative scarcity of flowering plants. Clusters of Chrysanthemum frutescens surrounded fine examples of Cordylines, and crescents of Abutilon vexillarium variegatum were also placed near the front, with a fine example of Spiræa palmata and a neat margin of Pteris tremula. Messrs. J. Laing & Co., Forest Hill, were second with a more formal but much brighter group, Lobelias, Gloxinias, Pelargoniums, Spiræas, Begonias, Coleuses, and Crotons being very freely employed; the margin of Adiantums, Lobelias, Gloxinias, Isolepis gracilis, and Coleuses being very pretty. Messrs. Hooper & Co., Covent Garden, were third with an attractive group fairly well arranged, and containing a good proportion of fine-foliage and flowering plants.

**MISCELLANEOUS.**—The large marquee was principally filled with collections and groups of plants from nurserymen, and by their

diverse character the taste exercised in the general arrangement and the satisfactory quality a handsome, bright, and effective display was secured. The General Horticultural Company staged a handsome group at one end of the large tent, the background being formed of large specimen Palms and Ferns, the fore part of the group consisting of a bed of Adiantums and Selaginellas, from which arose Crotons, Gloxinias, Dracænas, and Anthuriums. The central group of small Crotons, superbly coloured and very healthy, added much to the beauty of the group, which was honoured with a large gold medal. Mr. B. S. Williams, Upper Holloway, exhibited a large and choice collection of stove and greenhouse plants, Orchids, &c., comprising many very fine specimens. A silver gilt Flora medal was awarded for the group. Messrs. J. Carter & Co., Forest Hill, staged a large crescent-shaped group of Petunias and Coleuses, the former being well flowered and the latter highly coloured. The Petunias comprised the varieties named—Blue Vein, Stars and Stripes, Purple Prince, Maltese Lace, Queen of the Roses, Double Rosette, and White Pearl, all very distinct and good. A silver-gilt Flora medal was awarded.

Messrs. J. Laing & Co., Forest Hill, exhibited a handsome group of Tuberous Begonias, considered by many to be the finest, both in extent and the quality of the varieties, that has been shown by one firm. A large number of varieties was represented, including many novelties, some of which are described on another page. A silver-gilt Flora medal was awarded. Messrs. H. Cannell & Sons, Swanley, Kent, staged a very handsome group of Zonal Pelargoniums in pots, spikes of Foxgloves and Delphiniums being arranged in lines between them, the edging being formed of the variegated Jacob's Ladder. This group was greatly admired by all visitors, and well merited the silver Flora medal awarded for it. Messrs. Barr & Sugden were accorded a silver Flora medal for a large collection of Iris blooms and many other hardy flowers. A bronze Banksian medal was accorded to Messrs. Osborn & Son, Fulham, for a pretty collection of hardy plants, among which the small Lapageria-like plant Philesia buxifolia, the bright purple Labiate, Prunella grandiflora, and the profusely flowering Campanula Scheuzeri. Messrs. Hawkins & Bennett, Twickenham, were adjudged a silver Flora medal for a group of Adiantum cuneatum, with a few clusters of Zonal Pelargoniums at the back and a line of the same in front, the edging being Selaginellas. Silver Banksian medal was accorded to Mrs. W. Brown of Hendon for a large and attractive group of Pelargoniums—compact, healthy, and flowering most profusely.

Some very pretty groups were contributed by the Royal Horticultural Society, one consisting of Gloxinias and Adiantums being especially admired. A fine group of Tuberous Begonias was also staged, the plants being in very satisfactory condition, and a brilliant array of Zonal Pelargoniums was greatly admired.

A silver Banksian medal was accorded to Messrs. Hooper & Co. for collections of English Irises, dwarf French Poppies, and Delphiniums. The same firm also had stands of dried Grasses in the north-east quadrant. M. Lemoine, Nancy, France, had a group of seedling Pelargoniums, which were highly commended. Messrs. Downie and Laird contributed a handsome collection of Violas, and were awarded a bronze Banksian medal. Mr. Hooper of Bath sent flowers of Carnations, Picotees, and Pansies. Messrs. G. Bunyard & Co., Maidstone, had stands of Canterbury Bells and Sweet Williams; Messrs. Dick Radclyffe an ornamental rockery; Mr. J. R. Pearson, Chilwell, Notts, a superb collection of Zonal Pelargoniums; and a group of Cape Pelargoniums from Chiswick was highly commended.

#### SPECIAL PRIZES.

SEVERAL firms contributed prizes for groups, Begonias, vegetables, and fruit, and in most instances they induced good competition, the exhibits adding materially to the interest and extent of the display. The vegetables were, however, uncommonly abundant and excellent, the Judges experiencing considerable difficulty in many instances in determining the relative position of the collections.

**Groups.**—The General Horticultural Company very liberally offered six valuable prizes for groups, in two classes, for gardeners and market growers respectively, three prizes in each, value from £30 to £15, but strangely enough only two competitors appeared, and neither of these staged first-rate arrangements. It would almost seem that the large amount of the prizes had led to the general idea that the competition would be keen, and consequently many were deterred from entering. Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, Sussex, was adjudged a third prize for a good collection of fine-foliage and flowering plants, but not remarkable for the taste evidenced in the arrangement. Mr. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, was also accorded a third prize for a group consisting largely of Orchids, many very fine, but not disposed in any elaborate style. A large plant of Echinocactus visnaga was styled "The Savage," and an Odontoglossum vexillarium was termed "Civilisation" by way of contrast.

**Vegetables.**—As already noted a very fine display of these was contributed, a large proportion of the staging in the long tent being occupied with the various collections.

Messrs. Sutton & Sons' prizes.—These were for a collection of vegetables, twelve distinct kinds, any variety, and the competition was extremely good, a large number of very fine collections being staged, there being no less than thirteen exhibitors. Mr. Miles was first with an even collection of well-grown vegetables, comprising very

fine Leviathan Broad Beans, Culverwell's Telegraph Peas, Model Cucumbers, Nantes Horn Carrots, Early White Naples Onions, and Canadian Wonder Beans amongst others. Mr. C. Haines, gardener to the Earl of Radnor, Coleshill House, Highworth, Bucks, followed very closely. Mr. William Meads, Beckett Gardens, was third; Mr. J. Austin, Ashton Court Gardens, Bristol, fourth; Mr. E. Beckett, gardener to J. Plurrie, Esq., Sandown House, Esher, fifth; and Mr. Clarke, The Gardens, Melton Constable, East Dereham, sixth; all staging very creditable examples.

Messrs. Carter & Co.'s Prizes.—There was a very fine display of Peas in the classes devoted to them, and some remarkably handsome examples were staged. Five prizes were offered for four dishes, each comprising fifty pods, to represent Carters' Stratagem, Carters' Telegraph, Carters' Telephone, and Carter's Pride of the Market; twenty exhibitors appeared, thus staging the enormous number of eighty dishes, or four thousand pods. The first prize was accorded to Mr. G. Miles, gardener to Lord Carington, Wycombe Abbey, with uncommonly fine examples, the pods of great size and very full. The second position was accorded to Mr. H. Marriott, Prospect Place, Sherbeck, Boston, Lincolnshire, for collections very close in quality to the first. Mr. T. Bailey, gardener to T. T. Drake, Esq., Shardeloes,

Amersham, was third; Mr. G. Bartholomew, Hildenboro', Tonbridge, was fourth; Mr. John Garland, Killerton, Exeter, was fifth; all the prizetakers being extremely near each other in the quality of the exhibits.

Messrs. Webb & Sons' Prizes.—Three prizes were offered by the above-named firm for six distinct kinds of vegetables, and, like the other classes noticed, the competitors were numerous and the quality of their exhibits very satisfactory. Mr. W. Meads was first with fine Nantes Horn Carrot, White Naples Onions, Suttons' Telegraph Cucumber, Culverwell's Telegraph Pea, Canadian Wonder Bean, and Improved Lapstone Potato. Mr. Miles followed closely, Mr. Haines being third. There were nineteen collections staged.

Messrs. Rivers & Son offered a prize of £2 2s. for the best dish of six Lord Napier Nectarines. There were three competitors—Mr. C. Williams, The Gardens, Lower Eaton, Hereford, being the successful exhibitor, staging large, superbly ripened, and richly coloured fruits.

Messrs. Webber & Co., Covent Garden, offered prizes for the best example of packing fruit, the competitors to dispatch the packages from their gardens direct to Kensington, to arrive on the morning of the first day of the Show. There were only two entries. Mr. W. Crump, gardener to the Duke of Marlborough, Blenheim, Woodstock,

Fig. 120.—TAJ GARDENS, AGRA. (See page 534.)

Oxon, secured the chief prize with fine Grapes, Peaches, and Strawberries in shallow boxes. For the two former a thick layer of moss was placed in first, then a layer of cotton wool covered with tissue paper, upon which the fruit rested firmly and closely packed in the centre. The Strawberries were in leaves upon wool. Mr. A. Waterman, Preston Hall, Aylesford, had similar fruit packed without the moss, the tissue paper surrounding each bunch of Grapes and single fruit of the Peaches, the Strawberries being each wrapped in a leaf. In the first-prize collection the fruit was in excellent condition, the bloom upon the Grapes being very slightly rubbed.

#### THE PELARGONIUM SOCIETY'S SHOW.

VISITORS to previous exhibitions of this Society have, perhaps, seen a more satisfactory show than on this occasion both in regard to extent and quality; but taking the season into consideration most of the sections were very fairly represented—indeed, some handsome collections were staged in several classes, the Show and Zonal types being especially strong and well flowered. The Fancy varieties and the Ivy-leaf section were not in great force, but the cut blooms were all that could be desired.

*Show Varieties.*—These were numerously represented, mostly in fine condition. Mr. Wiggins, gardener to H. Little, Esq., had the best six specimens, even and well grown. The varieties were Victory, Illuminator, Jeanette, Magnificent, Prince Leopold, and Setting Sun. Mr. C.

Turner, Slough, was a close second, the plants not quite so large, but the blooms of unusual size and very bright; Claribel, Venus, and Mabel were very fine. The third prize was withheld. For eighteen specimens Mr. J. Wiggins was again first with an excellent selection of varieties, including Amethyst, Faust, Hermit, Christabel, Fortitude, Rosalind, Ritualist, Dauntless, and Superb in very fine condition. Mr. C. Turner again followed closely with a similarly fine selection; Joe, Constitution, Virgin Queen, Valiant, and Mountain of Light being noticeable, in addition to those named in the previous collection. Mr. Hammond, gardener to F. Hunt, Esq., Stamford Hill, took the third position. For nine specimens of the decorative section Mr. C. Turner secured the first prize with well-flowered examples; Kingston Beauty, Quadroon, Digby Grand, and Duchess of Bedford being particularly fine. Mr. J. Wiggins was second with neat specimens, Miss Bradshaw Improved being in very fine condition; Messrs. J. Hayes, Edmonton, taking the third position with smaller but freely flowered specimens. For eighteen specimens of the decorative section Mr. Wiggins was first with very good examples of Lucie Lemoine, Nellie Hayes, Princess of Wales, and Duchess of Edinburgh among others. Messrs. Hayes were second, their best plants being Olivette, Decorata, Madame Favart, and Triumphans.

*Fancy Varieties.*—Three collections only of these varieties were staged, and only two of these were of good quality. Mr. Turner was first with six specimens of moderate size, but very healthy and admirably

owered. The varieties were Princess Teck, Ellen Beck, Mrs. Hart, Lady Carrington, Fanny Gair, and Mrs. Popc. Mr. Wiggins followed with good plants, but a less even collection. The third prize was withheld.

*Zonal Varieties.*—These were particularly fine in several of the chief collections; the plants well grown, the flowers numerous, and the trusses large. For nine plants in 8-inch pots Mr. John Catlin, gardener to Mrs. Lermite, sen., was an excellent first with even specimens, remarkably well flowered. Alice Burton, pink; Cymbeline, scarlet; and Fanny Catlin, salmon, were very fine. Mr. J. Weston, gardener to D. Martineau, Esq., Clapham Park, was placed second with much looser but fairly good plants. Mr. Weston was also accorded a second prize for eighteen single Zonals. Mr. Catlin was first with nine double-flowered Zonals, staging very neat and compact specimens of Gorgeous, Lively, M. Thibaut, and Enchanting. Mr. J. King, gardener to G. Simpson, Esq., Wray Park, Reigate, was a good second with a bright collection, including several excellent varieties. Mr. W. Meadmore, Romford, was third with smaller plants, but in good health. There was an extensive display in the class for eighteen double Zonals, Mr. J. King securing the chief prize with an admirable selection of healthy plants; Mr. Catlin followed closely, and Mr. Meadmore took the third position.

*Ivy-leaf Varieties.*—Mr. Wiggins was first with the only collection of these Pelargoniums, the plants being very healthy and the varieties well selected. Sylphide, Mons. Dubus, A. F. Barron, Gloire d'Orleans, Sarah Bernhardt, Madame H. Rarat, Perle, Seedling 29, and Madame Emile Gullé were the varieties.

*New Varieties.*—Class 1, for Hybrid Pelargoniums. First, Messrs. Cannell & Son with leaves similar to some of the Cape species, the flowers being large, of good form, and purplish mauve in colour. Class 2, for Show varieties. A.—Three varieties. First, E. Foster, Esq., Clewer Manor, Windsor, with Margaret (Foster), large flowers, good form; the lower petals pink, very dark maroon upper petals, white centre. Royal Review (Foster), flower of medium size, even and fine form; lower petals scarlet streaked with a dark shade, upper petals very deep maroon, white centre; and Zealot (Foster), similar to the last, but with a larger flower, and without the streaks in the lower petals. B.—First, the Rev. A. Matthews, Grimby, Leicestershire, with Eva, fine flower, soft pink lower petals, dark crimson upper petals, good form and substance. Russell similar to Royal Review, but more salmon in lower petals, all of the exhibitor's raising. C.—First, Mr. Wiggins with Magnet, very bright scarlet, excellent form. Class 3, for Fancy varieties. A.—First, Mr. Turner with Sims Reeves, Florence Taylor, Queen of the Hellenes, excellent varieties. Class 4, for decorative varieties. A.—First, Messrs. J. J. Hayes with Ruby, Grand Lilas, and Mr. Ashby.

*Cut Flowers of Pelargoniums.*—Mr. C. Turner secured the first prize for thirty-six blooms of the Show varieties, with excellent examples very large and richly coloured, the varieties being best in commerce. Mr. Meadmore secured the chief prizes for twenty-four single and the same number of double Zonal blooms, very fresh and bright. For thirty-six double Zonals and twelve Ivy-leaved varieties Messrs. H. Cannell & Son, Swanley, carried off the principal honours with highly creditable blooms of very fine varieties. Mr. G. Duffield, Winchmore Hill, was first with large and bright blooms; Mr. George, Putney Heath, taking a similar award for twelve Ivy-leaf varieties in fine condition.

Certificates were awarded for the following new varieties:—

*Duke of Albany* (Foster).—A handsome Show variety, with very large flowers of good substance and excellent form. Lower petals scarlet-salmon, upper very dark maroon with a narrow edge of scarlet, and a white centre. Exhibited by Mr. Turner.

*Mr. Ashby* (Hayes).—One of the decorative section, being profuse in flowering, scarlet with a pinkish tint at the base of the petals, the upper being veined with a darker shade. Shown by the raiser.

*Annie Hemsley* (Hemsley).—Also a decorative variety, with soft salmon-scarlet-coloured flowers edged with white, the upper petals being blotched and veined with dark scarlet. It is a very free and attractive variety. Exhibited by Mr. Little.

*The Abbot* (Foster).—Another fine Show variety of similarly good form. Lower petals scarlet; upper very dark, nearly black, and possessing a peculiar velvety gloss. Exhibited by Mr. C. Turner.

*Magnet* (Wiggins).—A Show variety of great promise. Flowers large, smooth, of good substance, bright scarlet; the upper petals having a dark blotch. One of the brightest-coloured varieties. This and the two following were shown by Mr. Little.

*Superb* (Beck).—One of the Show type. Flowers of great size, bright crimson; very dark upper petals, white centre. Free and effective. Exhibited by Mr. Little.

*Britomart* (Beck).—A Show variety. Soft crimson lower petals; upper darker, with narrow margin of white.

*Belle du Jour* (Lemoine).—One of the Decorative section, with double flowers produced very freely. Exhibited by M. Lemoine of Nancy, France.

#### THE EVENING FETE.

THE weather proved very favourable for the Fête on Tuesday, and in consequence it was a most brilliant success, there being a remarkably large attendance of visitors. All the tents, the conservatory, and the upper part of the grounds were thronged throughout the evening. The grounds were illuminated with Messrs. Siemens' electric lights and Messrs. Z. D. Berry's coloured oil-lamps, the latter taste-

fully disposed amongst the branches of the trees, in wreaths round the trunks, and in festoons over the Lily tanks. The tents were lighted by the Anglo-American Brush Electric Light Corporation, the north-east quadrant arcade with the Maxim Incandescent Light, and the north-west quadrant by Messrs. Siemens Brothers' electric light. The bands of the Second Life Guards and the Royal Horse Guards were in attendance, and a performance by the Royal Criterion Handbell Ringers and Glee Singers was given in the conservatory during the evening. All the arrangements were highly satisfactory, and the fête may be fairly characterised as one of the most pleasing and successful the Society has held.

#### THE TAJ GARDENS, AGRA.

WE submit another view of these gardens that were referred to last week, and it is pleasing to observe that gardening is being so well and intelligently carried out in this ancient historical old station, once for magnificence and commerce the first city of India. It was the court of the great Akbar nearly three hundred years ago, on whose palace a thousand labourers were employed for twelve years at a cost of three millions of rupees. But the splendour of this former place has departed, and the gardens for which it was remarkable are changed with the lapse of time. From this city to Lahore, a distance of five hundred miles, is said to be the finest avenue of trees in the world, the road being canopied with foliage the entire distance.

In the Taj Gardens that have been so much improved of late, we are informed there is a large variety of trees, shrubs, and plants from nearly all parts of the globe. At the entrance to the right there is a Conifer plantation, and on the left there is a palmatum, both thriving equally well. One of the main points in the new arrangements has been to have as much lawn as possible. The designs are simple. Everything pertaining to fantastic, angular, and intricate forms and shapes has been avoided. All designs of beds which would be likely to clash with or pretend in any way to imitate the floral and ornamental designs which are so conspicuous in all the buildings have been carefully eschewed, and the result is a garden at once attractive and enjoyable. The picturesque character of this garden is shown in the engraving.

This view having been taken from the circular Rose garden. The naked tree is *Bombyx pentandrum*, and is over three hundred years old. It measures 45 feet round the base. The hole in the upper part of the trunk is where a large limb was blown off in a storm fifty-two years ago.

#### WHAT PLANTS USE.

(Continued from page 484.)

**WATER.**—Having disposed of air, light, and heat, water may next be referred to. Water forms three-fourths of the whole bulk of plants. It conveys the food which the plant finds in the soil to the leaves, and thence to every part of the plant. It is evaporated from leaves in immense quantities. Many actively growing plants under bright sunshine and a high temperature evaporate more than their own weight of water daily. Chief among these are Vines and Peaches, especially the former. This fact needs pressing home on the minds of cultivators, for it is only by understanding that Vines are ceaselessly pumping water from the soil that a proper idea of the amount of water that must be applied to borders can be formed. We are very decidedly of opinion that fruit trees, and more especially those under glass, often fail for want of a proper amount of water. No matter how thoroughly a Vine border may be soaked with water, if the drainage is as it ought to be, the soil firm and yet porous, one week of hot dry weather will render a further application necessary. Badly drained borders are not referred to. These remarks apply to good borders filled with roots. New borders which are as yet unfilled, or old borders from which the roots have wandered, do not come under the rule. Not only is the soil dried by the extraction of water by roots, but a by-no-means inconsiderable quantity escapes by evaporation. That which is drawn by the roots can only be supplied by fresh applications; but that which is drawn by evaporation may be, to a great extent, prevented from escaping by proper mulching. Where the rainfall is great or the water supply ample, mulching may be omitted, but where either are insufficient it becomes of the greatest value. Its application, especially on thin soils with a hard subsoil, often means success, when without it success would be quite impossible. Mulching is generally associated with stable litter, and is therefore neglected because the untidy appearance of litter cannot be tolerated. Leaf soil, spent tan, cocoa-nut fibre, or even siftings of soil from under the potting bench, are of the extremest value for mulching, and may be used liberally even in the flower garden without offence, but the opposite rather; for the use of such will induce

the plants to grow so much more rapidly that with an inch or two of such material over the surface, beds and borders will be much more speedily filled than without. Indeed in hot seasons it often happens that on thin soils many beds and borders get thinner instead of filling up. Surely a mulching of even roughish material, which would speedily become hid, is much better than this. We have gardened when without heavy watering, requiring much labour, or thick mulchings, such plants as *Violas* and *Calceolarias* failed to grow at all, but an inch of decayed sifted manure alone over the surface, caused a luxuriant growth.

The amount of water evaporated by trees against hot walls is often exhausting, and when this is accompanied by dryness in the soil much mischief follows. The attacks of red spider are oftener caused by aridity in the soil than the air. It is only, or chiefly, when trees are stinted of water that these do much

Fig. 121.—*Gillenia trifoliata*. (See page 529.)

mischief. Luxuriant foliage seldom suffers; stunted foliage is often destroyed.

Mulching is preferable to watering even where water is plentiful and can be easily applied. Evaporation not only carries the water out of the soil, it carries the heat too. Water may even be frozen by its own evaporation under certain circumstances. Let anyone fill a pitcher with water on a hot day and wrap a towel round it. Place the pitcher in a shady but airy spot, and keep the towel constantly wet. Place a thermometer in the water, and you will be convinced that heat is carried away by evaporation. Now we seldom want to lower the heat in the soil. A cold soil is against the well-being of all plants that need the artificial help of glass houses or sunny walls. A cold soil will counteract the influence of warm air. Plants are benefited by warm air because it warms them, but it will, to a certain extent, fail in this if the ascending sap be cold; and as evaporation from the soil produces cold, we ought to prefer mulching to watering, and when watering becomes a necessity mulching ought to follow in order to

prevent the necessity of its re-application and the escape of invaluable heat.

It may seem a strange thing to advocate, but we say that watering should only be done in showery weather. It often happens that there are a few showery days consecutively, and yet not more than enough to damp the surface and reduce evaporation to a minimum. Then is the time to supply water. In hot weather artificial irrigation, unless it be very thoroughly done, is useless and worse, for the air soon licks it up. When the air is damp, and yet the rainfall trifling, is the time to irrigate with the greatest success. At the same time irrigation when thoroughly done—that is, when the ground is flooded—is a great help on dry soil during drought, especially if mulching be applied immediately after. In the kitchen garden mowings from lawns and other short grass are of great value, but even when these are not available a loose layer of soil will do much to prevent evaporation. The free use of the hoe, whenever the soil is dry enough on the surface to be easily worked, will accomplish this to a great extent.

So many excellent directions for watering plants in pots have appeared from time to time in the *Journal* it is not necessary to consider it particularly in this place. It may, however, be pointed out that mulching might more frequently be applied to plants in pots, especially in summer. Plants that are outside, and even those in houses, become dry at the root in a very short time, and often need water twice a day. This means a very rapid evaporation, and consequently a very low "bottom heat." In many instances a mulching of rich manure, accompanied by plunging in ashes, would do much to prevent this, and also feed the plants, thus proving doubly beneficial. Evaporation from pots cannot well be avoided altogether, but glazed pots are better in this respect, and in others, than common ones. The idea that the porosity of the latter is beneficial is now an exploded theory. To prevent evaporation from pots as much as possible watering should be done whenever possible in summer time in the evening.

For irrigation purposes, whether for a single pot or broad acres, rain water is best; after that comes pond, brook, or river water, and lastly spring. It is seldom that rain water is harmful, but it sometimes happens in the neighbourhood of chemical works that it is impregnated with noxious acids and other matters to an extent that makes its repeated use destructive to plants. Sometimes brook and pond water contains iron to a hurtful extent; but this can be seen, for then the water makes a red deposit which betrays the presence of the iron. Brooks and rivers which flow through fertile districts are often positively enriching, but generally speaking the plant food contained even in drain water from fertile fields is so small that it may be left out of account in estimating its value for garden purposes, although benefit has often been derived by meadow land from such waters. Some spring water is very suitable, but it often contains lime, and to many plants, Heath plants more especially, lime is very hurtful. When such waters are used for syringing it leaves a coating of lime on the leaves, fruit, &c., and this is very objectionable. Water containing lime may be made nearly pure by boiling it; even exposure to the air will cause much of the lime to settle. Where quantities of water are required large tanks are necessary if the water is to be improved by this means. In many instances lime is present in the form of bicarbonate; in this state it is soluble, and does not separate from the water. If newly slaked lime or lime water is added the added lime seizes on part of the carbonic acid and the whole becomes carbonate of lime, which is insoluble and may be readily filtered from the water. Waters containing iron may be purified by exposure, and especially so if it is collected in large tanks, from which it can be run without disturbing the deposit. Generally speaking, however, it is far better and far cheaper in the end to build brick and cement tanks in the ground where it may be run off or pumped as required.—SINGLE-HANDED.

(To be continued.)

#### COTTAGE GARDENING—MAKING THE MOST OF SPACE.

A LITTLE garden sloping from the dwelling house southwards to the road, but raised above the level by a low stone edging and protected by light painted open wooden fencing. Looking upwards the house wall exhibits a crimson Boursault Rose tree in full blossom; an Ayrshire climber close by, for the first time weakly even in foliage; a Moorpark Apricot, formerly an ample bearer, now much shattered, and to be replaced in autumn by a profitable Plum. At the house door, approached by low steps, bushes of the old crimson China Rose, plants of common Musk (*Mimulus moschatus*), tufts of *Echeveria* with spikes of brilliant orange-coloured flowers, patches of *Mignonette* here, and there bushes

of Stonecrop well trimmed in; in the middle just between the windows a very large pot of *Alyssum maritimum*, a smaller one also at each end of the border, which like the three other borders is about 2½ feet wide, and a little way in front on the gravelled space where never a weed is to be seen two pots of *Saponaria ocymoides*. These five pots are masses mound-shaped of white and rose-coloured blossoms, yet exceedingly airy and elegant, the pots being quite outgrown and overgrown on every side, and the general effect most attractive.

The border under the house wall is in spring full of Snowdrops now at rest. In the centre of the gravel space is a circular bed gorgeous with Crocuses in their season. Now first within the neat Box edging comes a planting of dark blue Lobelias, the rest filled this year with scarlet Geraniums. The west border, besides the little Box edging common to the four borders, has a low-growing Privet fencing 22 or 23 inches high. Along the foot of this, indeed in all the borders, rows of wild Primroses nestle round with sweet-scented wood Violets and wild Hyacinths thickly studded between. The east border is bounded by a raised grass edging falling gently to the broad way that leads through a gate at the side of the garden up to the house and round to the back entrance. On each side of this gate grow some tall white Rose trees, Nature's own standards—several bare stems, then dense heads of darkest green, the white buds innumerable just bursting into bloom. On the right hand, well sheltered from the east, is the tiniest triangle not 2 yards either way; where at the foot of these standards are tufts of Primroses, wood Hyacinths, and quantities of flowering Lily of the Valley, out of bloom now.

Once more. Within the garden I have endeavoured to describe are to be found half a dozen Fuchsias, white, crimson, double—vigorous plants for autumn flowering that have stood the last few winters protected only by a covering of ashes. Petunias have been raised from seed sown in the open border sheltered from frost by a brick or two; these with rows of Victoria Asters and African Marigolds will make the autumn display; now Pansies, double red Catchfly, Mimulus, Feverfew, yellow Persian Roses, yellow Stonecrop, and two other plants about whose names I am uncertain, with one or two double Pinks to be succeeded soon by Clove Carnations, a little dwarf Hybrid Perpetual Rose, cover but do not overerowd the ground of this always healthy and admirably managed garden.

I should say that the possessors are intelligently devoted to their garden, finding time amidst home duties late and early to attend to the wants and habits of their plants. For Pelargoniums and Lobelias they have an empty room in the next cottage. The Fuchsias and Echeverias stood in the open ground. Little or no manure is used in the garden: a more certain result, it is found, is obtained by now and then taking away some surface soil and replacing it by earth in which Potatoes have been grown and which for the Potatoes had been well enriched.

On the house wall facing the east a Pear tree is grown, fruitless this year; a very fine Bigarreau Cherry running round even to the north is loaded with fruits.—A. M. B., *Mid-Lincoln*.

[We are informed that this garden is worked entirely by the daughters of the owner, and it would be an advantage if more of the daughters of England were to engage in similar healthy and pleasant pursuits, and make cottage homes generally bright and cheerful.]

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 25. NEW SERIES.

UNLIKELY as the circumstance might seem at first, considering that the study of such tiny beings appears a very dry subject indeed, the history of mites is not without its comical aspect. The observers of their habits have been perplexed by some of the results of bringing the microscope to bear upon them, since this has at times shown mites in a form or position that seemed mysterious. For instance, a mite has been noticed twisting itself about until the skin cracked, and a very different mite in aspect came forth—an example, some said, of a mite being the prey of another species almost as large as itself. Afterwards it was supposed that in this and similar cases there was only a transformation from the larval to the perfect stage, rapid and not gradual. And in several of the groups (a specimen of which we show) the larva of a mite is unlike the adult mite. Then, again, amongst the Hypopidae some species have been thought to undergo at least six or seven changes before reaching maturity, and brisk have been the discussions as to the nature of these, and whether the possession of six legs only is always significant of a larval condition. The water mites may be dismissed with the remark that it is believed they are mostly carnivorous, attacking larger insects or else feeding upon very diminutive infusoria.

The beetle mites with a horny thorax, that is of a blackish or brownish colour, are believed to be as plentiful in England as they are in France; but only two or three species have been noted as natives of these islands, the best known of which is *Damaeus corticulatus*, to which has been given the English name of the "black stone tick." These mites may be found in parties during the winter months under pieces of Pear bark that have been loosened by some means; in warm weather they scatter about on the trunks or branches. If it be necessary to interfere with these mites, as Curtis supposed, the winter would be the period to catch them *en masse*; but Boisduval pleads in their behalf, and certainly on his showing they are friends not foes to horticulture. He has seen them busily engaged in devouring aphides, and thrips in all its stages, and believes that these and similar pests are the natural food of the black stone tick. About Paris the species has been taken in hothouses as well as on fruit trees, though not in England to my knowledge. The young tick has only six feet; the adult is as large as the head of an average pin, and it breathes by means of two curious tubes in the neck. It has no eyes seemingly; those organs are in fact lacking amongst the beetle mites generally. Others of them are partial to moss, especially in damp spots, and specimens have been taken at Spitzbergen, proving that they are a hardy race.

The family of the Tyroglyphidae have received the popular appellation of cheese mites bestowed upon them by some naturalists. This is incorrect, because the substance indicated only furnishes food to a part of them. Thus one species is familiar to every collector of insects as the devourer of the fleshy or fatty portions of specimens kept in boxes and cabinets. Other species have their points of interest to the gardener. These mites have soft and smooth bodies, with jaws or mandibles that in shape resemble the claws of a crab. *Rhizoglyphus echinopus*, with no melodious name, is injurious, though not to a great extent; it is a white globular mite, fond of secreting itself amongst the scales of Liliaceous plants, especially during autumn. It has often been detected upon the Hyacinth, and Mr. Murray thinks the species also resorts to the roots of various plants. Like many of their brethren they will crawl off the substance they frequent on to the skin of any human being near, causing an irritation though not making punctures.

Another species in the above genus is of importance from its presumed connection with the Phylloxera; Mr. Riley, reporting upon it from the United States, asserted that when young this mite imbibed the juices of roots injured by the Phylloxera, and afterwards attacked and ate the root-haunting type of this foe of the Vine. Hence some suggested that if the species *R. phylloxerae* could be naturalised in Europe it would check the increase of a formidable Vine pest; but a French student of these and other mites discovered them upon the roots of the Vine, and he could not perceive that they interfered at all with the Phylloxera. Other insects in the genus *Rhizoglyphus* seem restricted to vegetable food, and so it is highly probable that the mite in question only comes to feast upon the fluids that are exuded through the proceedings of the Phylloxera, with which it does not meddle. *R. Rostro-serratus* is about the size of a cheese mite, grey in colour, and with a curious series of humps along the back. It occurs in large parties upon cultivated Mushrooms, which, in the course of a day or two from their being first infested by the mite, become black and putrid.

The very abundant cheese mite we mention only briefly. It bears also the name of *Tyroglyphus siro*. Gardeners, like other folks, occasionally make a dinner or a supper off bread and cheese, and many like the latter all the better should it be "mitey." But some naturalists have endeavoured to show that by the promiscuous swallowing of cheese mites there may be originated divers internal complaints in the human subject. It is possible that in very exceptional cases these may manage to live in the stomach and multiply there. Ordinarily they are doubtless soon digested, and no harm ensues. As, however, a rather too accurate observer has stated that the devourer of mitey cheese eats not cheese only but "eggs of mites old and new, larvæ, cast skins, perfect mites, excrement in minute greyish balls, and spores of microscopic fungi," the savoury article has its unattractive if not its unwholesome aspect. A relative of the cheese mite taken in North America, *T. malus*, is useful because it devours the mussel scale of the Apple; it is a long-bodied, smooth, short-legged mite. In Ceylon *T. translucens*, a very small species, subsists on a coccus that occurs upon the Coffee plant. Mites, it may seem amusing to state, have peculiarities in their modes of progression. Those species just described walk along deliberately with the head lowered between the first pair of legs; the sugar mites run briskly; and the mites in the genus *Cheyletus* move by a succession of jumps, holding the while the

jaws extended so as to seize anything they may be inclined to attack. The Cheyleti lead a wandering life, hunting up other mites that are feeding in parties, amongst whom one of these makes itself quite at home, destroying speedily a goodly number, for it only sucks the juices of its prey. It was found to be quite impossible to keep several Cheyleti together in a box, as combats took place at once and continued until but one survived. A very pretty mite under the microscope is Glyciphagus plumiger, with circlets of radiating hairs; it hides in walls, especially those that are damp. The food is at present unknown.

There has been recently much discussion concerning the influence of electricity upon vegetation, more particularly in reference to its power of inducing rapid growth or increasing

Fig. 122.—Watermite (Hydrachna) magnified.

Fig. 123.—Larva of Hydrachna magnified.

productiveness. It has also been supposed by some who call themselves men of science that electricity, rightly managed, could produce both animals and plants. By the constant operation of an electric current upon a stone moistened with an acid solution, an experimenter in this line several years ago succeeded as he thought in creating some new mites, one of which became the subject of much comment under its name of *Acarus horridus*. But this "horrid" creature, it was ere long discovered, was no novelty at all, it was merely a *Tyroglyphus*, the portrait of which the artist had somewhat improved!—J. R. S. C.

#### KITCHEN GARDEN.

A GOOD breadth of Parsley may now be sown, and where it is much in request during winter some should be sown in a pit to be covered with glass when cold weather commences. Plants from previous sowings must be thinned to about a foot distance. A good sowing of Turnips should be made for autumn and early winter use. Early Stone or Six Weeks, Veitch's Red Globe, and Orange Jelly are suitable varieties. Where young Carrots are much required the Early Horn section may yet be sown, and will come in useful for late use. Another sowing of French Beans may be made if desirable on a warm border; also Peas of the earlier varieties. The earliest crops of Peas will soon be over, and the ground being forked over no unnecessary delay should elapse in occupying it with Broccoli and such vegetables as are most in request for winter. A liberal sowing of Lettuce must be made from the 10th to the 14th of next month, giving preference to the Cos varieties, such as Hicks' Hardy White, Brown Cos, and Bath or Brown Sugarloaf, as many of these plants will be required for lifting into frames or elsewhere for late autumn. About the same time the main crop of Endive can be sown, Round-leaved Batavian, Green Curled, and Picpus being suitable. Leeks should be planted out in well-manured trenches and liberally supplied with water in dry weather. Afford copious supplies of water and liquid manure to Celery, earthing up the earliest crop, and planting out for succession. As the gathering of succeeding crops of Peas is completed the ground can be utilised for late Celery, not omitting a large breadth of that excellent little Cabbage Rosette Colewort. A reservation must be made of ground for Winter Spinach. No time should be lost in placing out Cauliflower plants to produce heads for

autumn use, also the autumn and early winter Broccoli—such as Veitch's Protecting and Snow's Winter—affording a good and preferably a sheltered situation. Preparation will soon have to be made for sowing the Tripoli section of Onions. The superiority of these for early summer use being well known, it is only necessary to note the fact, so that due consideration may be given this important crop. Ground that has been occupied with spring-planted Cauliflowers will be cleared in time to be followed by Tripoli Onions. Take up Shallots as soon as they indicate ripeness, and store them in bunches or otherwise. Keep down weeds, and ply the hoe freely in favourable weather between the rows of growing crops that are not mulched. Attend to nailing and tying up Tomatoes as they advance in growth, removing all side shoots when the requisite number of fruiting shoots are obtained. Train, thin out, and stop ridge and Gherkin Cucumbers, and do not allow those or Vegetable Marrows to have insufficient water.

#### STRAWBERRIES FOR FORCING.

For forcing, whether early or late, the runners cannot be layered too soon. Layer them into the pots the plants are intended to fruit in, or into 3-inch pots, and when well rooted detach them and transfer them to the large size. We prefer the latter method as most convenient, the pots not being crooked but filled firmly with turfy loam chopped moderately small, adding about a sixth of well-decayed manure and a twentieth part of bone meal or Clay's fertiliser. A row of pots is half plunged in every alternate space between the rows of plants that were placed out early the previous season to afford strong runners. A small hollow is made in the centre of each pot, and the runner introduced and securely pegged in position. By having the pots in alternate rows sufficient runners are obtained from the two rows on each side to occupy the pots arranged closely together, and the watering is rendered easy, and gathering the fruit is practicable without disturbing the pots. It is important that runners be layered from fruitful plants. Water as necessary to facilitate rooting. After trying most kinds we find La Grosse Sucrée, Vicomtesse Hericart de Thury, and Keens' Seedling the best, as named for early forcing, President for succession, James Veitch for size; Sir Charles Napier, Dr. Hogg, British Queen, and Cockscorn being excellent for late forcing.

#### FRUIT HOUSES.

*Vines.*—Late Grapes, particularly those that have to hang during the winter months, will require more thinning than those for autumn use, otherwise they will not keep in good condition. The laterals should not be allowed undue extension, except where there is sufficient space to avoid interfering with the principal foliage. Vines bearing Grapes that are swelling must have liberal supplies of water or liquid manure, both for inside and outside borders. Maintain a moist genial atmosphere by damping the surface of the border or the mulching material; also damping available surfaces at closing time with guano water. High and dry borders do not as a rule in seasons like the present receive sufficient water, as healthy Vines in active growth require a very large amount, provided the drainage is good. Ventilate freely with a temperature of 70° to 75° by day artificially where Grapes are colouring, and 80° to 85° or 90° from sun heat, employing sufficient fire at night to prevent the temperature falling below 65°, as Grapes ripened in a low temperature do not keep well, and are not so highly flavoured as those ripened in a brisk heat. Early Vines from which the Grapes are cut may be syringed every evening, in order to preserve the foliage as long as possible, and allow a moderate extension of the laterals, for if the Vines are permitted to rest too soon second growth will commence. Keep the border fairly moist, and allow a free circulation of air night and day.

*Melons.*—As houses become cleared of fruits remove the plants and make the necessary preparations for collecting the fermenting materials, if such be employed for bottom heat, and soil also previous to a fresh start. The old soil must be entirely removed and the house cleaned. Where bottom heat is supplied by fermenting materials only a portion of them need be removed and a little hot dung worked in, which will revive the bottom heat sufficient for this time of year. Pits and frames may be treated similarly, for unless the plants that have fruited are vigorous it is better to remove them and supply healthy young specimens than to rely on weakly and probably

insect-infested plants for a second crop. Plant on ridges or hillocks rammed down firmly, and maintain a moist atmosphere. Pot seedlings, and keep them near to the glass to ensure a sturdy habit. Feed plants liberally that have swelling fruit, and keep the growths thinned. Fruits that are ripening should be exposed to a free circulation of air and plenty of light. Cracked fruits may be guarded against by withholding water from the atmosphere after the fruit commences ripening, and afford it to the roots only to prevent flagging. Keep a sharp look-out for canker at the collar, and apply freshly slaked lime to the affected parts. Continue to set the flowers daily, and directly the fruit is swelling earth up the roots. Plants in frames do not set fruit freely, sometimes owing to the atmosphere being too moist, which renders the pollen inert; a little ventilation constantly will remedy the defect.

#### ORCHARD HOUSE.

Peaches, Nectarines, Plums, and Pears have their fruits swelling. In order to encourage this as much as possible afford rich mulchings and liquid manure, this being more especially necessary where the trees are carrying full crops and the roots are restricted to the pots. Examine the trees frequently, and disbud or pinch back strong shoots, preserving as far as possible the symmetry of the trees, but avoid removing too much foliage at one time, as this is calculated to render the trees unhealthy. Maintain a moist genial atmosphere by syringing every evening when the weather is warm, closing the ventilators somewhat early when it is likely the nights will be cold. Fig trees whether in pots or planted out will require great care in watering, keeping them well supplied, for if they receive a check now it is probable the fruit will fall. The points of strong-growing shoots should be removed and weakly ones rubbed off, keeping them fairly thin so as to allow air and light to have access to every part. Cherries are now ripe, and syringing must cease or the fruit will be spoiled. If possible the trees should be moved to a separate structure where the atmosphere can be kept dry and cool, in order that the fruit may remain in good condition as long as possible, protecting it from birds with netting; or the trees may be placed in some part of the house by themselves, so that syringing them may be avoided. Where Vines are trained under the apex of the roof or over the pathway the shoots should be stopped one or two joints beyond the bunch, and trained-in to the wires so that they do not shade the trees too much; the laterals must be kept to one joint by stopping as required.

#### PLANT HOUSES.

*Stephanotis* grown in pots and trained on trellises may, if the plants are not already large enough, be encouraged to grow for some time; but if already as large as required, they may at once be so treated so as to harden their growth without inducing them to extend any more, placing them where there is moderate heat with a dry atmosphere, and more air than where they have been grown, only giving water to prevent the leaves from becoming flaccid.

*Rondeletia speciosa major*.—This is very desirable for late summer and autumn flowering, blooming freely and lasting long in beauty. It succeeds in a cool stove, and grows well in good fibrous loam with about a sixth of sand. Plants started early are now showing flowers, and must be allowed abundance of water. Their bright red trusses are good for cutting and last some time. If the flower heads are cut off when the flowers have faded the plants will commence growing again and flower a second time.

*Pancretiums* are fine for cutting, the individual flowers combining purity of colour, elegance of form, and fragrance. They are of easy growth, thriving best in good loam with a little sand. When in active growth afford water freely, but when at rest give only sufficient to keep the foliage fresh, for if they are then over-watered the soil becomes sour, and the roots perish as fast as they are formed. They also require a light position.

*Clerodendrons*.—Of these *C. fragrans*, *C. fallax*, and *C. Kämpferi* have bright distinct flowers and are easily grown, yet the plants are seldom seen. They flower twice in the year if well managed. Plants started early will now have flowered, and should be shortened back to a couple of joints below the flower heads and placed in heat. If well supplied with liquid manure they will soon produce a second lot

of flowers, and as they open inure the plants to a lower temperature, transferring them to the conservatory, where they will be found valuable in the autumn. *Æschynanthuses* grown in baskets must now be well supplied with water, or they will not flower freely. *Amaryllis* should have liquid manure and be kept free from red spider. The plants must also have light well-ventilated positions, or the growth will not attain the development essential for flowering strongly.

*Greenhouse*.—Hardwooded plants that were potted early in spring have now taken to the soil and will be much benefited by being at once transferred to larger pots, especially young plants of *Acacias*, *Adenandras*, *Boronias*, *Eriostemons*, *Darwinias*, *Pimeleas*, *Polygalas*, *Leschenaultias*, and *Statice profusa*. The size of the pot must in all cases be determined by the condition of the roots. In no case, however, let the pot be larger than is likely to be fully occupied with roots before winter. If bright dry weather follow the potting shade for about three weeks from sun, and maintain a moist atmosphere, not allowing more air than is necessary to prevent the temperature rising too high. This potting must not be deferred longer than the ensuing fortnight, as it is important they become well established before autumn. *Salvia splendens*, *S. gesneræflora*, *S. Heeri*, and other winter-flowering Sages may be finally potted and placed outdoors where they have shelter from wind, at the same time full exposure to the sun. If the pots are plunged in ashes it will save watering and assist the plants to retain the lower leaves. *Heliotropes* for autumn and winter flowering may be treated similarly, removing all flowers as they show until September, and supply liquid manure. *Veronica salicifolia* and *V. Andersoni* are useful autumn-flowering plants, and to have them dwarf and bushy the pots must be plunged in coal ashes in a sunny situation, supplying water freely, and when the pots are filled with roots liquid manure will be beneficial.

Encourage winter-flowering plants of *Cytisuses*, *Genistas*, *Acacias*, *Correas*, *Bouvardias*, *Linums*, *Monochætums*, and *Daphnes* to promote a free sturdy growth and enable them to flower freely. Any needing repotting must be attended to at once, so that they may have the pots filled with roots before they are placed outdoors to ripen the growth. *Epacris* growing vigorously should have a light position, closing the house somewhat early in the afternoon, and syringe the plants.

*Azaleas* that flowered early and which were potted a few weeks ago must have the growth encouraged, and shading may now be dispensed with, or only some light moveable material employed in the brightest weather. Any plants that appear weak can have clear liquid manure every alternate time water is required. Later-flowered plants should have the seed pods removed, and be encouraged to make all the growth possible. Shade will be necessary at starting, but afford all the light possible without direct exposure to the sun.

## THE BEE-KEEPER.

### THE AUTHORSHIP OF "MODERN BEE-KEEPING."

In the "British Bee Journal" for June an editorial note calls attention to and endeavours to deny a statement made in this Journal in a reply to a correspondent that I am the author of "Modern Bee-keeping." As a duty I owe to my fellow readers I append my reply to my censor, adding that as a rule I disregard all attacks in the before-mentioned Journal, seeing that their aim and object must be well understood by all discerning bee-keepers, while I regard a conscientious and consistent course as a sufficient and abiding defence.

In the June number of the "British Bee Journal" exception is taken to a statement made in the *Journal of Horticulture*, in which I am referred to as having written gratuitously "Modern Bee-keeping." The character of the editorial is irritating enough, but I would prefer to reply to it in the strength of gentleness.

It is only needful now for me to say that not only did I gratuitously write the whole of the second edition of "Modern Bee-keeping," and the whole of the first except a very few lines of Mr. Hunter's, retained by me in order that his name might not disappear from the preface, but that in addition I designed and

drew upon the blocks nearly all the euts, and thus saved the Committee several pounds, while I even paid for the wood out of my own pocket. The preface is nearly all Mr. Peel's, who kindly wrote it at my request, and not at the request of the Committee.

As a bee book "Modern Bee-keeping" is wholly mine, and I am glad that the profit derived from its sale has tended much to improve the financial position of the Association. There is honour in service; and if the fact that some of this honour is falling on me has awakened jealousy in the minds of any I can give such my pity, and hope that if too much selfishness has hindered their usefulness the hindrance may be taken away.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

#### INCREASING STOCKS.

I HAVE received a letter from a correspondent on this subject, and as the questions contain matter for a general lesson on increasing stocks I shall venture to quote part of the letter touching the difficulty referred to. "I set aside a straw skep to breed from exclusively, having other hives devoted to honey-gathering. First I took a swarm of fliers (the bees flying about) and gave them a Ligurian queen. Next I took a large swarm with old queen from the straw skep. Lastly I took another swarm with young queen. For a week I watched if the young queen would commence laying, but at the end of a whole week she had not laid, so I thought she had not been fertilised before swarming. A double difficulty cropped up here, for I came to the conclusion that as the young queen had not been fertilised before leaving the old hive, which had no other queen in it for over fourteen days, that there was neither brood nor eggs in the old hive from which to rear a young queen. So I have put the young queen back into the old straw hive till she is fertilised and goes on with her laying; and into the new-made hive (presumably the second swarm hive) I have put the Ligurian queen, leaving her family to make a queen for themselves."

If our correspondent had stated when these movements were made, or how soon the one followed the other, it would have been easy to have told him what was right and what was wrong in them. His first move was to catch or guide the bees flying about into a hive having a Ligurian queen. This I consider was a risky and unwise proceeding. He knows whether it answered or otherwise. After this he took a large swarm with the old queen. This was right, and quite in harmony with good practice and natural laws. Lastly he took another swarm with young queen, not knowing whether the old hive had a queen or egg left in it. Our correspondent now sees his difficulty, and wants to know how the young queen remained so long unfertilised in the old hive, and for a whole week in the new hive. Perhaps she was fertilised, perhaps she was not. Fertilisation may take place three days after birth, and it may not take place for twelve or fifteen days after. Only one queen have I known fertilised so late as the fifteenth day of her age. Queens are not fertilised till swarming is completed, and sometimes piping continues for six days before second swarms are cast off. After swarming has ended weather may prevent queens leaving their hives in search of mates, and even in fine weather they may be unsuccessful for some days in their outdoor trips. When successful excursions have been made some days pass before queens commence laying. This explanation will show that no one can exactly tell how soon the Ligurian hive will have a queen hatched, fertilised, and laying. If an average swarm had first been taken with the old queen from the straw hive, and then given it the Ligurian queen, it would have been better, for from the straw hive (with Ligurian queen) two or three more swarms might have been had, and from the first swarm a virgin swarm. Thus moving on safe and natural lines the stock would have been multiplied into five or six good hives. In all such proceeding it is well to assist Nature, not wise to fight against it.—A. PETTIGREW.

#### SHALL WE CULTIVATE MELLIFEROUS PLANTS FOR OUR BEES?

THAT the place occupied in Nature by bees in general, and the honey bee in particular, is, as a rule, not understood even by the bee-keeper himself, is certain; and he in consequence is often led into expenditure which he would not otherwise have incurred, while he is not unfrequently met by disappointment which a little greater knowledge would have prevented. Let me in order to make this clear explain that the business of the bee as a honey and pollen gatherer, although most interesting to us as bee-keepers, because upon this our profit rests, is after all but the least part of the work which the insect accomplishes in the great and wondrous scheme of Nature. The bloom secretes honey, but not for itself;

it is a gift to the honey-gatherer—nay, rather a payment, for the bee in its visit to secure food for itself and young unconsciously performs an act which completes the object of the flower's existence, and receives the honey as a compensation for its service. This subject is so full of marvels and is so various in its details, that anything beyond an illustration or two I cannot at the present attempt. There always seems so much to write about that off questions like these get pushed on one side, but perhaps the winter may supply further opportunity. Speaking broadly then, honey-bearing flowers have anthers which shed pollen, while at a certain period a central organ or organs of the bloom (stigma or stigmata) open and wait for pollen being placed upon their surfaces. When this occurs a pollen tube, as it is termed, grows down from the pollen granule to the ovary and enters the ovule, which henceforth passes into a new phase of its existence as a fertilised developing seed. Without this placing of the pollen granule upon the stigma the bloom remains expanded for an unusual time, but at length fades, leaving no seed behind. The placing of the pollen granule upon the stigma can hardly be accomplished without the intervention of insects, for almost all blooms present some curious correlation of parts which makes it difficult, or even impossible, for its seed to be fertilised by pollen it has itself produced. Cross-fertilisation and not in-breeding is the law for a reason amazing by its beauty. This crossing is secured by means which are legion, but amongst which two are the most common—viz., the anthers ripen first, and not till all their pollen is gone does the stigma become receptive (protandrous), or the stigma is first produced, the anthers not ripening till after an opportunity for fertilisation by other pollen has been given (protogynous).

It is a general rule that honey continues to be secreted till fertilisation takes place, when a diversion of nutrition occurs, and with the ceasing of the honey the petals, Nature's coloured flags hung out to attract the insect visitant, drop. The netting of the greenhouse or conservatory against insects is of course right, because here bloom and not seed is the object desired.

But all this has a very practical application, for bee-keepers are prone to believe that their success depends upon the immediate surroundings of their hives. This mistake is seen in greatest intensity in a question I have been scores of times asked—"Do you think bees would succeed with us, we have a number of flowers in our garden?" To this it might be replied, Bees do not depend upon garden flowers, but if they did the fact of the flowers being in your garden would render them nearly useless. Is it not clear that the work the bee has to perform can only be accomplished by its scattering widely; and if its instinct led it to alight upon the very first bloom before it as it issued to forage that bloom would, in ninety-nine cases out of every hundred, have been already rifled, and so possess nothing to offer, while the honey further a-field would be left untouched and there seed would be unfertilised. I have this year grown two long rows of *Limnanthes Douglasii*, an excellent honey-bearing annual, very free-blooming, and decidedly protandrous, so that bees are required for its seeding. I have twenty-three stocks of Cyprian or Ligurian bees standing at an average distance of 60 or 70 feet from these plants, while I do not know that any black bees could be found under one-third of a mile from my house. The *Limnanthes* has been alive with insects, the hive bee exceeding all others in number; but I examined these plants several times daily for eight days in succession, and saw during the whole time but one Ligurian bee upon them, all the others being blacks.

That bees will in times of scarcity visit at the very door of home *Sedum fabaria*, or even such poor honey-yielders as *Geraniums*, I know, but at the same time would denounce as a mere delusion (what a scientific view of the case must dispel) that the planting in small gardens of the finest melliferous flowers will ever at all materially improve the position of our stocks.

Let us not discourage this honey-production, however, for—my *Limnanthes* to wit—if we do not thus much help ourselves we do a little towards helping others. The scattering of Clover and Borage seeds, and such like, in waste places on railway banks and disregarded corners, or in our grounds if extensive, is very useful, because here we conform to a natural instinct which we neglect if our blooms are made to nod their heads in the very face of the bees as they start from the alighting board. I have been told not a few times by disappointed purchasers of seed packets potentially containing whole supers of honey that the plants represented to be so suited to bees were quite unvisited. I hope I have now made the reason apparent. This year, in watching my Cherry trees about 70 yards from my hives, I found but few yellow-banded bees amongst them in comparison with the number seen on those of a neighbour at four or five times the distance.

It is thus by wide diffusion that the multitudes of bloom get in the main their needed attention, and that their honey is not provided in vain.—FRANK R. CHESHIRE.

(To be continued.)

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Ferneries (Sussex).**—There is a description of Mr. Bewley's garden at Rockville on page 499, vol. ii., of this Journal; and descriptions of the gardens at Manley Hall in vols. xv. and xvi.

**Pear Leaves Blistered (East Berwickshire).**—Your trees appear to be infested with the Pear tree blister moth, the particulars of which and remedy appear on page 475 of our issue of the 9th inst. Possibly also the roots have entered a wet subsoil. If this is so, draining the land and replanting the trees in good soil are necessary, afterwards mulching over the roots with manure; the work to be done in November.

**Pelargonium Leaf Spotted (Wrenshall).**—The injury has not been caused by an insect, but is a disease that affects plants the root-action of which has been defective at some time; possibly the soil has been too wet and the atmosphere of the house too close. We should remove the affected parts, and if one plant only is injured plant it in the open ground, and it may outgrow the disease.

**Echeverias (Idem).**—There are many species suitable for bedding, but it is impossible to say whether they are more compact than yours, the name of which you do not mention. Careful management is necessary for raising Coleuses from seed, and even many gardeners fail in securing plants by that method. They are more generally increased by offsets and inserting the leaves in sand, the pots being placed on the stage of a greenhouse, and much care exercised in watering. This, however, is a slow process, and only good cultivators are successful with this mode of increase. A temperature of 55° is requisite for wintering Coleuses, but 60° is better, while some of the hardier forms may be preserved if the temperature falls occasionally to 50°, the plants being kept rather dry.

**Fumigating Melons (D.D.).**—You have no doubt injured the plants. Two or three light fumigations on successive nights are always safer and more effective than one powerful dose of tobacco smoke. If there are insects still on the plants, syringe them and dust them while wet with tobacco powder or snuff. By keeping them quite free from insects and maintaining a genial temperature the plants will probably recover.

**Onion Attacked by the Maggot (E. B. M.).**—We fear there is no remedy for the plants that are so seriously attacked, as the Onion fly deposits her eggs within the leaf sheaths of the plants, and the maggots form in the centre of the bulbs. Various preventive measures are recommended that are more or less effectual, and which will be referred to, also the other questions, in a future issue.

**Grapes Ripening (A Reader).**—If your Vines are healthy and growing freely you need not be alarmed about the wood ripening; we like to see it ripen with the Grapes if the Vines are strong.

**Insects on Vines (A.C.).**—There are no insects on the Vines except red spiders, and these we could wash off with the syringe. Fumigation is of no use, but you might apply sulphur, paint the hot-water pipes, and heat them until the sulphur fumes are perceptible; or sponge the leaves with a solution of soft soap or nicotine soap.

**Pansies (L. J. K.).**—All the flowers are Show varieties except 3 and 5, which are Fancies; the former of these is worthless and not deserving a distinguishing name, the latter too withered to judge as to its merits.

**Grapes Shankling (L. M.).**—From the description given it appears that you have treated the Vines reasonably, and the quantity of piping named would be quite sufficient. Shankling is generally caused by overcropping or defective root-action, the latter arising from stagnant soil causing the roots to decay, or a very dry border causing them to shrivel. You do not say whether the border is in a good moist condition, nor yet the extent of the crop allowed. We suspect the defect is traceable to one of these matters.

**Parcels Insecurely Packed.**—We frequently receive specimens sent in such fragile boxes that they are quite crushed in transit through the post. We also occasionally receive plants and sprays without numbers and without any letters in reference to the specimens. Now and then we receive parcels from which the contents have escaped. This week we received a small, broken, and empty paper box bearing the Manchester postmark. A direction label has also come to hand which had been stamped at Liverpool, the parcel to which it was attached having presumably been lost in transit. Correspondents who do not find any reference to what they have sent may well bear such facts as these in mind.

**Lilium Monadelphum v. Szovitsianum (W. H. H.).**—The state of the Lily bloom was not such as to enable a very correct judgment to be formed.

Enough, however, was apparent to say that it is a variety of Monadelphum, if not Monadelphum itself, the latter being probably the case. A note from Mr. James McIntosh, a large and successful cultivator of Liliums, refers to Monadelphum, as follows:—"The Lily was first introduced, I believe, as 'Monadelphum Szovitsianum,' it afterwards became known as 'Colchicum,' and now is frequently called 'Colchicum Szovitsianum.' I transcribe an extract from Mr. H. J. Elwes' Monograph of the genus Lilium, which is instructive—'Lilium Monadelphum (the Caucasian Lily), abundant in many parts of the Caucasus, at an elevation of 4000 to 6000 feet. Likes a strong soil in England. Scent disagreeable to some, pleasant to others. One of the earliest of flowers. Ripens seed freely in most seasons. Seed germinates quickly, but the seedlings grow slowly, and Mr. Ellacombe reports do not flower till the tenth year after sowing. Introduced by Messrs. Loddiges early in the century. There are several varieties which are fairly distinct, but run into one another so closely that I think better to follow the high authority of Mr. Baker in considering them as varieties only. I would here point out, though I am not at all confident, that these two forms, Monadelphum and Szovitsianum, can in all cases be well separated, yet as a rule they may be distinguished by several characters, among which the colour of the pollen, which is red brown in Szovitsianum and lemon yellow in Monadelphum, is the most conspicuous. Monadelphum is also from a fortnight to three weeks earlier in flower, and when first showing above ground usually has its flower buds exposed, whereas in Szovitsianum they are concealed by the leaves until the plant is just ready to bloom.' You will thus be able to determine the nomenclature of your plant, but from what we could see of the colour of the pollen we conclude the name is L. Monadelphum.

**Heating Pit (H. Taylor).**—In order to heat the pit satisfactorily it will be necessary to have a flow and return pipe for it. We should have a branch pipe put in at D, and bring the pipe above the bench, this being of course the flow pipe, and then take it beneath the bench so as to join the return pipe from the greenhouse at D. Instead of employing 4-inch pipes as in the greenhouse, 3-inch would give you sufficient heat in the pit, indeed more than sufficient to exclude frost.

**Erecting Greenhouse (B.).**—Your sketch is totally insufficient. No one can inform you as to the proposed sufficiency or otherwise of piping in houses unless not only the form and aspect but the length, width, and height of the structures are named. Besides, you show 240 feet of 4-inch pipes in the new house, and ask us in your letter if 2-inch pipes will be sufficient. If you send an amended plan and make your case clear to us we will readily advise you on the subject; with the data you have afforded it is quite impossible for us to answer your letter usefully.

**"Pelargonium-flowered Pansies" (L. J. K.).**—We do not know a section of Pansies distinguished by the above term by any accepted botanical or horticultural authority. It is no doubt a fancy name applied by some cultivator of Pansies, the blooms of which did not appear to him to properly belong to either the Show or Fancy sections. With the view, however, of aiding you to obtain what you require we make your desire known by quoting from your letter—"I wish to obtain the name of the foreign grower of Pelargonium-flowered Pansies, as I am desirous of obtaining plants of named varieties. The great English growers of Pansies say that they have none of that sort; but as I have seen flowers I know that some nurserymen abroad must grow them, and as Pansies travel well by post plants could easily be sent if I knew to whom to apply." If those who have any "Pelargonium-flowered Pansies" will send us blooms of them the information sought shall be conveyed to our correspondent.

**Dagmar Peach (G. S.).**—The fruit you have sent was much crushed, but judging by the glands on the leaves and the peculiar gelatinous flesh we think it of the above variety, which is described as follows in the "Fruit Manual":—"Fruit round, and marked with a shallow suture, which is deepest at the apex. Skin very tender, more than usually downy, of a pale straw colour, almost entirely covered with minute crimson dots, so dense that they nearly form a solid mass of colour; but here and there small patches of the yellow ground colour show through and give the appearance as if the fruit were mottled with yellow. Flesh white, with a gelatinous appearance; it is so tender as to melt entirely away in the mouth, and the flavour is very rich and vinous. Flowers small. Leaves with generally kidney-shaped glands, but occasionally they are round on the small leaves. This is one of the varieties which exhibit various formed glands on the same plant. This ripens about the 10th of August. It was raised by Mr. Rivers, and is the second generation from Early Albert, which he also raised, and was named in honour of Princess Dagmar of Denmark, sister of the Princess of Wales."

**Marechal Niel Rose (L. G. S.).**—If you permit the growths to extend under the influence of light and air, thinning out any of the shoots to prevent overcrowding, but not shortening the others, they will be firm and mature in the autumn, and will produce flowers freely in the spring. The pruning in winter must be limited to the removal of the immature tips, the growths remaining practically their entire length.

**Morello Cherries Falling (F. J., Cork).**—There are several causes that result in a portion of the fruit dropping—imperfect fertilisation, spring frosts occurring at a critical time, an excess of fruit beyond the strength of the tree, and immature wood, the consequence of overcrowding and the absence of sun and air in the autumn. You manage your tree differently from the method ordinarily adopted and recommended. If you had read attentively the instructions that have been given from time to time in "Work for the Week" you would have perceived that after thinning out, by disbudding, superfluous growths the remainder should be secured to the wall their entire length between the main branches, precisely the same as Peach trees are managed, as both Peaches and Morello Cherries bear chiefly on the wood of the current year's growth, as also do Black Currants. Yet we have seen good crops of Morello Cherries on the spur system of management; the other, however, is the more certain, and we advise you to try it. The young growths when secured to the wall must be sufficiently thin to allow of the full development of the foliage, as overcrowding is a common source of failure.

**Daisies and Plantains on Lawns (P. K.).**—The presence of Daisies in great numbers is usually indicative of poorness of soil, but it by no means follows if manurial dressings are applied that the weeds disappear. The best of all remedies is to dig up the lawn, carefully forking out all the weeds, and cleaning the land, then adding if possible a surface dressing of good soil, free from the roots and seeds of weeds, and sow the whole thickly with clean lawn seeds obtained from a nurseryman or seed merchant, and not swept up from the hay-loft. By this practice a fresh verdant lawn may be had in a few weeks. One drop of sulphuric acid placed quite in the heart of each plantain will destroy those weeds, and we have seen Daisies eradicated by Watson's lawn sand, and occasionally we have seen it fail; in the latter case possibly the instructions for use had been deviated from in some apparently simple yet important respect. These should be strictly carried out in every particular.

**Names of Plants** (*L. S., Surrey*).—1, *Hedychium Gardnerianum*; 2, *Asplenium cicutarium*; 3, *Doodia media*; 4, *Adiantum tenerum*; 5, *Pteris tremula*; 6, *Davallia dissecta*. (*Iota*).—*Periploca græca*. (*J. T. S.*).—It is impossible for anyone to name with accuracy sprays of plants simply enclosed in letters, which are not only crushed into a shapeless mass, but quite shrivelled by remaining in the post office throughout Sunday. We can only suggest that the blue flower is *Centaurea montana*; the other is totally unrecognisable. (*Reader*).—1, *Valeriana officinalis* (common Valerian); 2, *Atriplex hortensis* (garden Orache); 3, *Oxalis stricta* (Upright Wood Sorrel); 4, *Ægopodium Podagraria* (Herb Gerard, or Gout Weed). (*Rosa*).—The Orchid was insufficient; send another specimen. The other plant is *Asarum canadense*.

**Removing Sections** (*Buzz*).—Sections are almost always found most nearly complete towards the centre of the tray or rack. If the honey yield is good and likely to continue we simply draw out the full boxes and replace empty ones, but if we know we are drawing towards the close of the harvest we contract the rack, removing the finished boxes and pushing the remainder together. We think it a wise plan to watch for the close of the honey yield and then take our nearly-completed boxes from our weaker hives and place them over one or more of our strongest, feeding with extracted honey if necessary in order to get all into marketable condition. This plan may exclude the sections from exhibition, however, the matter turning upon the wording of the schedule. Feeding with extracted honey is costly, and will only pay for mere finishing. The honey so fed must be diluted with quite an equal quantity of water, as with thick honey the bees are unable to work freely. The sealing made from fed honey is always exceedingly white and pure, as it is free from propolis, the presence of which often sadly stains and freckles the late autumn gathering.

#### COVENT GARDEN MARKET.—JUNE 29.

TRADE somewhat improved during the week, and with good supplies prices easier. Large quantities of Strawberries are now reaching us from the home counties as well as the south, and prices this week will be at their lowest.

#### POULTRY AND PIGEON CHRONICLE.

##### THE DISEASES OF SHEEP AND LAMBS.

THIS subject is one of the most important to be considered by the manager of the home farm. Disease and difficulties attending the shepherding of the flocks are of daily—nay, frequently of hourly—occurrence; and not only are there diseases which may be brought out by the action of the atmosphere and the food consumed by the animals, but there are disorders which termed hereditary, and some are incidental to ewes either during pregnancy or at the time of parturition. It should, however, be remembered that although many of the losses of both ewes and lambs at the time of yearning cannot be called diseases, yet they have an effect often attended with more serious consequences than any epidemic. In consequence it will be necessary to point out what diseases and disasters to which sheep and lambs are liable are due to the general management and treatment by the home farmer and his shepherd. It will be necessary, too, to understand and define diseases which cannot be controlled or prevented,

and those which may be prevented by anticipatory management. It is of the utmost importance to consider how many of the causes of disease are within our control, and those which are purely the result of atmospheric influence; on the other hand, how many of the diseases attending our flocks are really due to neglect and inconsiderate or inexperienced management. The home farmer will see most clearly the direction his course must take, and it will be our endeavour in writing upon this subject to aid him in understanding and surmounting the difficulties he will encounter. It must be admitted that the home farmer having the management of sheep stock has daily opportunities of witnessing the commencement, progress, and termination of disease occurring on the farm, and by studying the causes said to produce them he will be enabled in a short time to treat them successfully.

The first portion of the subject is the diseases which have proved so fatal to flocks in various counties and districts of England during the several past wet and cold seasons. We find that the mortality arising from causes such as the rot applies chiefly to the grazing districts where the animals live principally upon pasture lands; but as an article was given in this Journal of July 31st, 1879, upon the subject of the rot or coathe it is unnecessary to enlarge upon the subject on this occasion. We may, however, take this opportunity of stating that through the influence of the late unfavourable seasons for sheep they have suffered largely from another disease affecting the liver without the presence of any flukes, although the symptoms are frequently mistaken for the true rot. It consists from some undefined cause of changes in the constituents of the bile, producing white streaks and spots and general paleness of the liver, and ultimately so far destroys the ordinary secreting functions of the liver as to produce an impure quality of blood and its necessary consequences, such as dropsy and gradual wasting of the tissues of the body. These diseases, being always aggravated by an excess of moisture, have been materially augmented for several years past by the extraordinary amount of rain that has fallen. On a post-mortem examination of several animals which have died under wasting symptoms we have found the livers greatly enlarged, and which would break readily between the fingers. This is called "sand rot," but it is often termed "dry rot." It is generally believed to be caused not only by an excess of moisture on the herbage and the soil, but also by the deposit of sand on the grass by floods. We have often seen this silt on the grass on very poor clay soils after the subsidence of water, the result of excessive rains, which does not quickly disappear by absorption in these strong soils; but although this disease is incurable it is preventible. The way in which this silted and tainted herbage acts upon the system is not only an interesting but an important question, quite worthy of study by our professors of veterinary pathology.

On taking up another point we must observe it is notorious that in some districts, especially in the southern and eastern counties, a great mortality of lambs has occurred for some years past, and that these losses are now continuing to increase as the yearning period comes round, and these losses have fallen upon the lambs about and soon after lambing. From the early age at which the lambs die there is no time for disease to be engendered in their systems; we must therefore carry our inquiry as to causes back, and see if we cannot discover some predisposing causes connected with the system of breeding and management carried out by our flock masters in the above-named districts. At any rate, we will give a few hints for consideration on this part of the subject. First with regard to breeding. We fear very much that the hardihood and constitution of the male animals in many of our breeds of sheep have suffered in no slight degree from the practice now so general of forcing them to an unnatural size and fatness at an early age, with the view of making them appear larger and better on the day of sale than they would be if reared in a

more simple and natural manner. We can, however, hardly expect breeders to discontinue the practice while they find the public prefer buying the animals in such an artificial state. Secondly, we think that if the males have been too artificially fed by the flock masters that the females, on the other hand, have been injured to some extent by the adoption of the opposite system. No doubt most people have been stimulated by the high prices of mutton for the last few years to turn out as great a number of animals as they possibly could, and have thus been tempted to keep a larger number than they could maintain in a healthy condition. Now, anyone can readily understand that disease may be, and often is, engendered in the offspring when the blood of one parent is in an unhealthy and plethoric state from overfeeding, and that of the other in a poor and unhealthy state from underfeeding. We would suggest that they who have erred from either or both of these reasons should be very careful to have male animals not artificially fed and reared, taking care to select the breed best adapted for our purpose, while we would give the females every indulgence consistent with good health and condition, and try to increase the quantity of mutton by a greater weight per carcass.

The losses of lambs to which we have just referred has often been attributed to the animals having been fed upon roots, the produce of applications of concentrated manures to almost all the food crops on which the flock masters of certain districts keep their sheep, and may have had some effect on the organisation of the plants, and that has again operated injuriously on the sheep. We, however, with the greatest confidence oppose the theory that any losses of sheep or lambs were owing in any degree to the use and application of artificial manures.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Horses, and oxen too, are still fully employed on the land, for although the working of oxen is not carried out to so great an extent in some districts, yet in various counties they are nearly as much in use as formerly, except in those instances where steam power is used. We cannot recommend the home farmer to exclude oxen from the tillage labour of the farm, for when compared with horses there are various practical points in their favour, more particularly when the best kind of animals either of Sussex, Hereford, or Devon breeds can be obtained. We estimate their comparative value for working purposes as we have placed them, taking the Sussex first as being the stronger, and the Devons last as being the smaller and weaker animals of the three. The value of the ox for labour should be estimated like that of the horse, according to its size, weight, and activity. We have not space now to enumerate the comparative advantages of the two animals for working purposes, especially as we have previously referred to this matter on the working power of animals in these pages. The preparation of land after green crops for sowing Turnips will still be going on, and we prefer sowing at once, ploughing, drilling the seed and manure every day as fast as the land is ploughed. This plan is certainly the safest in our changeable climate, for by sowing as fast as the land is ploughed we are sure of obtaining a fine surface upon all except the strongest soils, and a sufficiency of moisture. There is sometimes the fact to be considered how best to dispose of the Couch, if there should be any found after the green crops are removed. If it is present the land should be first scarified, dragged, harrowed, &c., and the Couch carted away, unless the weather is very dry. It may then be burned to save time. After this by ploughing a moderate depth the land may be again worked fine, and the grass picked off after drilling the seed; for that is a matter which must not be delayed, otherwise the seed will not vegetate if the weather is very dry. The odd horse, ox, or mule kept for various work on the farm will now be fully employed, and in some cases one or two more horses will be wanted for carting green fodder for the cattle. In addition to this there will be horse-hoeing Mangolds, Swedes, early Turnips, Cabbages, and other root crops. This hoeing should always be done without reference to the weeds being very strong, because stirring the soil will always be beneficial in dry weather. At the same time we must not wait for the weeds to become strong, for when young they are more easily destroyed. Irrespective of the weeds the second hoeing is a necessity, and in the case of the Mangold plants being weakly or sickly  $1\frac{1}{2}$  cwt. of nitrate of soda per acre should be strewn along between the lines before the horse-hoeing is done. Horse labour will still be required with the mowing machine. Strong horses should be used and changed at mid-day, so that no horse in this work may be worked longer than about four or five hours. The mowing will require to be continued if the weather is fine, the crops generally being little if any more than half a crop either of field grass or upland and parkland. In dry weather we need not fear having too much work on hand, because machinery gives the opportunity of getting over a lot of work in a little time. The hay, also, requires but little labour or attention, for in really hot dry seasons we have known pasture hay cut one day and carried to stack the next day without any tedding whatever; and this is the best plan with light short crops, because when taken up out of swathe there is then neither waste or loss of the small fine grasses.

*Hand Labour.*—Men are now employed in carting bays to the appointed place for making the hayricks, so that the stands may be made and ready at short notice for the commencement of rick-building. Unless in very small occupations, or in case the hay is near the farmstead, the stacks are best made in the field where the hay was produced, as so much work can be done in a short time in such a case—a matter of immense importance at the busy period. The home farmer should obtain a skilled thatcher for constant work on the farm, or teach and engage one of his best labourers to prepare for the work.

*Live Stock.*—Now the weather is favourable the stock, whether of cattle feeding for beef or dairy cows grazing for the milk supply, have been doing well, although the grass has not been very abundant. It has been the same with sheep; the weather during the period of folding off Clovers, Vetches, and Saintfoin has been favourable, and all land intended for roots after the green crops will work fine for drilling and seeding. The lambs which have been weaned, and are required for early sale, should have a full allowance of cracked beans or grey peas, unless as we find some farmers are now employing Mangold cut and mixed with cake or beans in the meal state; and where it can be done, and the Mangold has been reserved, this is the best means of feeding without waste. Breeding sows should now be accommodated in a littered yard, feeding on green crops or grazing in a grass paddock or orchard with pease or maize in the troughs given twice a day.

#### VARIETIES.

*RAPID GROWTH OF GRASS.*—It will be remembered that at the Paris Exhibition of 1878 some surprising results were produced with grass seeds, but even these have been surpassed at the Derby Show ground of the Royal Agricultural Society. We are informed that on the 20th June Messrs. Carter mowed for the first time the grass which was sown on the afternoon of the 2nd June, the ground thus presenting a perfect sward in the short period of seventeen days from the time of sowing—the quickest growth of grass that has been recorded.

— *IPSWICH APIARIAN SHOW.*—We have received the schedule of prizes for hives and honey offered by the Suffolk Bee-keepers' Association to be competed for at the second annual Show, to be held on the 19th to 24th of September, 1881, inclusive, at Ipswich, under influential patronage. Thirteen prizes are offered for hives, two for supers, twenty-one for honey, four for wax, two for bee flora, and there are also special classes for cottagers. A honey fair will be held in connection with the Exhibition.

— *ART AND SCIENCE OF AGRICULTURE.*—Professor W. H. Brewer has written as follows in the Journal of the American Agricultural Association, a work of two hundred pages, containing much interesting matter and valuable information:—Agriculture is both an art and a science. The art of agriculture is very old, almost as old as the human race; the science of agriculture is very young, almost as young as some of the men who hear me speak. Before the modern means of transportation were devised, and before commerce had so placed all civilised nations into one brotherhood, when regions separated from each other by even moderate distance did not and could not stand in direct agricultural competition, when agricultural methods were simpler, and society's wants were also simpler, then the art sufficed very well to feed and clothe the people as they then lived. But now, when distant regions stand in sharp competition with each other in the markets of agricultural products, the science must play a more important part. The art still varies with the locality, with the soil, climate, the traditions of the people, and the thousand and one local conditions which control the agriculture of any particular place. The art is local and changeable, but the principles of science are fixed and general. The art must be changed or modified with each new invention, with new facilities for transportation or production; but scientific principles, remaining fixed, may, however, be applied in new directions with the new need or new conditions, or it can be applied in new ways to remove old difficulties.

— *THE IMPORTANCE OF PURE SEED.*—From the same source we cite the following by Dr. Albert R. Ledoux:—From a lot of commercial red Clover seed, a carefully drawn sample of 2 ozs. (59 grams) in weight was taken. It contained seeds of red Clover, 94 per cent.; impurities, 6 per cent. Of the 94 per cent. of pure seed, 60 per cent., or three-fifths, were found to be incapable of germinating. The impurities consisted of sand, chaff, and seeds other than red Clover. A pound contained no less than 14,400 foreign seeds. Pursuing the investiga-

tion still further, these unwelcome intruders were found to be of forty-four distinct species, as follows: Thistle, Horse Sorrel, Sheep Sorrel, Milkweed, Dandelion, Knotweed, Bottle-grass, Knawzel, Bladder Campion, Corn Spurrey, Star-wort, Penny Cress, Rabbit Clover, Swedish Clover, Zigzag Clover, Hop Clover, White Clover, Valerian, Speedwell, Blue Violet, Marsh Violet, Pansy, Rib-grass, Plantain, Timothy, Poppy, Forget-me-not, Black Medick, Burdock, Darnell, Cranebill, Goose-grass, Spurge Blueweed, Wild Carrot, Ox-eye Daisy, Pigweed, Chickweed, Winter-cress, Sand-wort, Pimpernel, Dodder, and Alyssum. While we might tolerate an occasional Forget-me-not, Pansy, or Poppy, and might welcome the Timothy and white Clover, who would want to sow the Blueweed, Daisy, Burdock, Darnell, and Dodder? From the data I have given, we can easily calculate that the farmer who sowed this stuff upon his field distributed with it the germs of 680 Blueweeds, 21,400 Dodder, 5983 Daisies per acre, to say nothing of the other useless or hurtful seeds to the number of 215,843 on every acre. We can now realise his misfortune; but this is not all. A single plant of Blueweed has produced by actual count 14,735 seeds, of which 8255 sprouted. What a world of trouble all this means! No wonder English farmers have the proverb—

“One year’s seeding  
Is seven years’ weeding.”

— BRITISH GOAT SOCIETY.—At a meeting of the British Goat Society held last Thursday, it was reported that a sum of £64 had been allotted as prizes for goats, £49 for mules, and £44 for donkeys, in connection with a show of these animals to be held at the Alexandra Palace on July 9th and following days, under the patronage of the Duke of Wellington. Mr. Holmes Pegler (Hon. Sec.) stated that he had already received a number of applications for tickets for the kid dinner fixed for the first day of the Show. Allusion was also made to the forthcoming exhibition of the Agricultural Society at Hatfield, when premiums to the value of £19 10s. will be awarded to goats, a portion of this sum being contributed by the Society.

— AGRICULTURAL PROSPECTS.—The hay crop is certain to be both late and light. Green crops are nothing like so promising as they were last year. Turnips have been sown and resown repeatedly after destruction by the fly. Mangolds are much riddled by the grub, which attacks them in a later stage of growth. Potatoes are very promising. As to the Wheat crop opinions are very various. Upon the whole, we think the impression made by these reports is favourable. The crop is late and in some places it is thin, but generally we trust there is a prospect of a fair average yield. Of the spring Corn, the Barley is generally looking better than the Oats, which have suffered from the wireworm and are patchy in many places. — (*Agricultural Gazette.*)

## POULTRY AND PIGEONS

### FANCIERS v. FARMERS.

A GOOD deal of discussion has been going on of late as to the effect which the development of the taste for fancy poultry during the last thirty years or so has had upon the food supply of the country. Has the table fowl of the country been improved? Have the laying qualities of our poultry been developed? Such are the questions asked. The answers are various. The “praisers of the time that is past,” declare that the Dorking of to-day is a miserable impostor. It has nothing, in fact, to recommend it to any other notice than a passing and general condemnation. It has black feet, it has big bones, it has coarse flesh, in a word it has everything that is bad. The winner of many prizes is not a Dorking at all; it is a mere spurious imitation of the real old Dorking produced by some cross which has indelibly stamped upon the race a taint which cannot be got rid of.

Now as the Dorking is essentially the table fowl of the country, these statements if uncontradicted would go a long way to prove that, so far as table fowls are concerned, the fancier has done his worst. Contradiction is, however, forthcoming in abundance. The successful Dorking fanciers of to-day assert that as table fowls their birds are better than they ever were, and there are not wanting independent witnesses to corroborate this view.

We shall not attempt to say which side is in the right, but setting the evidence on the one hand against that on the other, suppose that they mutually cancel each other, and that the show Dorking of to-day is at least as good a table fowl as the Dorking of a quarter of a century back.

If this view be correct the controversy as to the merits or demerits of the show Dorking may be dismissed, for if the fancier of to-day can offer to the poultry farmer only as good a table Dorking as was obtainable thirty years ago, he can also offer to him other birds which are suitable as the foundations of a breed of fine table fowl. He can further supply materials for the production of a good laying family, and thus turn the balance largely in his favour.

In much that has been written on this subject, the fact that the fancier does not as a rule much regard practical points has been alleged against him as a fault. It might with almost equal justice be alleged that pictures or statuary are not edible, and that therefore painters and sculptors are to blame for not improving the food supply of the country.

The fancier as a fancier has nothing to do with the food supply, and the fact that he chooses to exercise his taste and skill upon subjects which are also capable of being treated from a practical and utilitarian standpoint cannot render him blameworthy. Let the blame, if such blame be deserved, be laid at the door of the farmer in whose province these matters really lie, and not at that of the fancier to whom they are of minor importance.

We must confess that we think there is ground for the complaint that poultry and eggs, as items in the national food supply, have been neglected. During the last few years there has been to some extent a tendency towards improvement; but looking to the facts that many millions of eggs are imported annually into this country from France and elsewhere, and that French table poultry are far superior on the average to those produced here, it must be admitted that there is still much room for improvement.

An intelligent appreciation by the farming classes, especially the small farmers, of the capacities for development in this direction which are at their command, and of the profit which may be derived from a judicious expenditure of their time and capital, is what is really wanting to remedy the existing evils.

The fancier, though not directly concerned in the matter, has by his pursuit of size and symmetry as exhibition points, by the introduction from the continent of breeds which had always been bred there chiefly for their table qualities, and by the distribution far and wide over the country of pure-bred birds with certain known characteristics, placed at the disposal of the farmer the means of producing a breed of poultry which shall rival the short-horn as a layer-on of meat and be also remarkable for egg-production.

Many of the useful qualities of a breed are doubtless sacrificed by the fancier in his efforts to attain perfection in standard points; but it must never be lost sight of that but for the fancier certain breeds which are most useful for the purpose of crossing in with common fowls would hardly have been produced at all, and that the laying qualities which are lost by breeding for points can generally be recovered by introducing a cross of perfectly strange blood into the family.

The best results, both as regards table and laying qualities, which we have heard of have been attained by taking the products of fanciers’ labours, undoing the harm and retaining the good which had been accomplished, and then, regardless of fancy points, developing the useful qualities by careful selection and judicious crosses. This is the method which the poultry farmer will find most advantageous, and it is a method which would not have been open to him but for the efforts of the poultry fancier. Let the farmer, then, gratefully acknowledge the benefits which the fancier has conferred upon him, and avail himself of efforts which, though not made on his behalf, have resulted in enabling him to take up a neglected branch of his business with advantages which but for the poultry fancier he would not have possessed.

### THE MUSK DUCK.

WE have often remarked on the paucity of the breeds of useful Ducks as compared with the great variety of fowls, and have hailed with pleasure any pure and profitable addition to our duckeries. We are tempted now to write a few lines upon no new breed, but upon one with which most of us have been acquainted from our childhood, but which we have been wont to regard solely as a quaint curiosity, and have consequently neglected—we mean the Musk Duck. Perhaps we have been used to call it the Muscovy, but this name has been given it in error. It is undoubtedly the Musk Duck, probably first imported from

Peru, and so called from the odour of musk which pervades its plumage, and is quite pleasant in the beautifully soft down with which it lines its nest.

In the old poultry books Musk Ducks are somewhat fully described, in the modern ones they are passed over very cursorily. Dixon, who devotes a chapter to the breed, hardly, as it seems to us, does it justice. He says of the Musk Duck, "It will never go near the water if it can help it, but will prefer the farmyard, the precincts of the kitchen, or even the piggery itself, to the cleanest stream that ever flowed; in fact, it hates water except some dirty puddle to drink and dabble in."

When thrown into a pond it gets out again as fast as it can." Such is by no means our experience. The Musk Duck will not, like the Mallard or the black East Indian Duck, be continually found upon the water, but ours swim frequently and keep their plumage, which is white, in spotless condition. Any Duck which has been reared, as many are, under a hen and far from water till it is mature will always hate water. The Musk Duck is not peculiar in this respect. Its first peculiarity is the great disproportion of size between the two sexes, the drake being nearly twice the size of the Duck. Both have much curious coral-coloured flesh about the head, and both make peculiar subdued noises unlike the "quack" of the ordinary Duck. They perch, too, on fences and on trees; our own look very pretty established for the night on a fence running through a pond to keep the cattle from deep water. The male bird is certainly one of the largest of the Duck tribe, and may with advantage be used to cross with the Aylesbury or Rouen Duck. The produce of such a union are very large, attain the earliest maturity, and are delicious to eat; but it should be remarked that the Musk drake is generally very faithful to a mate of his own species, and if it is desired to rear cross-bred Ducks no Musk Duck should be kept. We have heard that when old the drake often becomes ferocious, and besides flying at human beings bullies poultry and other Ducks. We have not found ours do so. We have this spring bred from a single pair in a large enclosure round a piece of water with two or three other kinds of Ducks upon it. The Musk birds have kept to themselves, and have never in any way molested any of the others old or young. The Ducks are fair layers and the best of mothers. They make a beautiful nest of their down, almost equal to eider down, and which has a delicate musk scent. They sit (this should be well remembered) thirty-six days, and sometimes more. The Duck should be cooped for three or four days, and may then be allowed to range about with her family, which she will do most quietly and contentedly. The young are the prettiest and quaintest of ducklings and very tameable; they soon show their perching propensities by sitting on the edge of their drinking vessels. For the first month they should be driven into a dry coop or house at night. About food they are not at all particular, and will eat whatever is prepared for chickens or other ducklings.

The plumage of Musk Ducks is found pure black, pure white, and more often black and white or mottled brown and white. The self-coloured birds are by far the handsomest; we prefer the white, which is the colour of our own, for it is the purest white possible, like that of the Fantail Pigeon, and has none of the tinge of yellow so common on white fowls and other white Ducks. The black, too, are handsome birds, and the gloss and sheen of green and purple upon them is very bright, equal to that of the black East Indian Duck. Black, we are told, is the colour of the wild breed in South America. Audubon asserts that they make their nests in a wild state in trees or stocks of trees. We have never known them to do so in a domestic state. The young ones should be killed at ten weeks old if reared for the table, when their flesh will be found both rich and tender. There is something fascinating in the extreme tameness and confidence of the breed; the Duck specially struts about most calmly surrounded by her family, and quite free from the stupid fussiness of Ducks in general. Where many eggs are required we do not recommend them; but where there is room for variety and some tameable pets are desired, then decidedly Musk Ducks should be added to the aquatic stock.—C.

#### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at Charing Cross Hotel on Monday, the 27th of June, at 2 P.M. There were present Messrs. T. C. Burnell (in the chair), T. W. Anns, R. A. Boissier, A. Comyns, O. E. Cresswell, A. Darby, and L. C. C. R. Norris.

ELECTION OF MEMBERS.—The following new associate member was elected—L. W. W. Melhuish, 16, Erith Villas, Northend, Erith, Kent.

DISQUALIFICATION.—The complaint against Mr. C. Brown of Windermere, which had been several times previously under the considera-

tion of the Committee, was again brought forward. It was alleged by Mrs. Paxton, Oak Villas, Hamfrith Road, Stratford, that Mr. C. Brown early in December last sold and delivered to her a bird purporting to be the Buff Cochins cockerel, winner of cup at the Dairy Show, 1880; that he subsequently advertised another bird, also purporting to be the Dairy Show winner, for sale, and also advertised eggs for hatching from hens mated with that bird; and that Mr. Brown actually sent on approval to a friend of Mrs. Paxton the bird so advertised. Mrs. Paxton submitted letters written by Mr. Brown in support of her complaint. The Secretary had had considerable correspondence with Mr. Brown, without obtaining any explanation satisfactory to the Committee. It was resolved—

"That Mr. C. Brown of Lake Side New Hotel, Windermere, be disqualified for one year from the 27th June, 1881, from exhibiting at Shows held under Poultry Club rules."

OWNERS BIDDING AT SHOWS.—The Secretary submitted for consideration a draft of the case to be put before counsel as resolved at the last meeting, and such draft was approved by the Committee.

NON-PAYMENT OF SALE MONEY BY SHOW.—A complaint by Mr. A. E. Ward that the sum of £1 16s. due to him from a show held at Thornton on August 9th, 1879, being the proceeds of a sale (less commission) of a pen of Buff Cochins entered in the selling class at that show, had not been paid, was again before the Committee. The Secretary reported that he had written twice, on the second occasion by registered letter, to the Secretary of the Thornton Show asking for an explanation of the matter, but that he had received no answer to either communication. It was resolved—

"That Mr. A. E. Ward should be guaranteed his expenses, not exceeding £3, of recovering in the County Court the amount due to him for sale of birds at Thornton Show."

ACCOUNTS.—The accounts of the Club for 1880 were laid before the Committee, examined and approved, and it appeared that there was a balance to the credit of the Club as on December 31st, 1880, of £173 15s. 4d.

CLUB LIBRARY.—It was resolved that a Club library should be formed, and that Mr. Lewis Wright's collection of poultry books should be purchased to form the nucleus of such library.—ALEX. COMYNS, Hon. Sec. Poultry Club, 47, Chancery Lane, London, W.C., June 28th, 1881.

#### OUR LETTER BOX.

**Hen Crop-bound (N. S. R.).**—Your hen is crop-bound. Pour some warm water down her throat, and gently but thoroughly knead the crop for some time. This will distend and soften the crop, and a table-spoonful of castor-oil will probably clear away the obstruction. Should this not succeed you must cut open the crop near the top, making an incision through the outer and inner skin about an inch in length. Through this opening the contents of the crop must be removed with a small spoon, the crop thoroughly washed out, and any obstruction which may have lodged in the outlet removed. The opening must then be sewn up, each skin being stitched separately and each stitch distinct. Horseshair is the best material to use for thread. We have sometimes avoided the necessity for this operation by softening the food in the crop with a considerable quantity of water, holding the bird by the legs with the head down and the back against our knees, and gently but firmly pressing the liquid food through the gullet. This must be done with care and rapidity, or the bird may be choked in the process, and the food to be removed must be kept in a liquid or semi-liquid form by pouring in water from time to time until all has been removed. Whichever plan be adopted the bird must be carefully fed on soft food in small quantities for some time afterwards. Do not allow her to eat much grass for some time.

**Chickens Lame (Idem).**—It is probable that the lameness has been caused by an injury, as you suggest. Is there any wirework in which they might get their feet caught?

#### REMARKS.

19th.—Fine breezy day.

20th.—Fine; overcast at intervals; slight rain in evening.

21st.—Dull and overcast; very gusty wind; much finer latter part of day.

22nd.—Dull with slight rain in early morning; bright and fine afterwards.

23rd.—Fine pleasant day; cool breeze.

24th.—Hazy in morning; fine warm day.

25th.—Cool and showery; fine evening.

Temperature very uniform and rather above the average. No rain of importance except on Saturday.—G. J. SYMONS.
